PREFACE.

AND THE RESIDENCE OF THE PARTY OF THE PARTY

ALL diseases originate in the exuberance, deficiency, or retrograde action, of the faculties of the sensorium, as their proximate cause; and confist in the disordered motions of the sibres of the body, as the proximate effect of the exertions of those disordered faculties.

The fenforium possesses four distinct powers, or faculties, which are occasionally exerted, and produce all the motions of the sibrous parts of the body; these are the faculties of producing sibrous motions in consequence of irritation, which is excited by external bodies; in consequence of fensation, which is excited by pleasure or pain; in consequence of volition, which is excited by defire or aversion; and in consequence of association, which is excited by other sibrous motions. We are hence supplied with four natural classes of diseases derived from their proximate causes; which we shall term those of irritation, those of sensation, those of volition, and those of association.

In the subsequent classification of diseases I have not adhered to the methods of any of those who have preceded me; the principal of whom are the great names of Sauvages and Cullen; but have nevertheless availed myself, as much as I could, of their definitions and distinctions.

The effential characteristic of a disease consists in its proximate cause, as is well observed by doctor Cullen, in his Nosologia Methodica, T. ii. Prolegom. p. xxix. Similitudo quidem morborum in similitudine cause eorum proximæ, qualiscunque sit, revera consistit. I have taken the proximate cause for the classic character. The characters of the orders are taken from the excess, or deficiency, or retrograde action, or other properties, of the proximate cause. The genus is generally derived from the proximate effect. And the species generally from the locality of the disease in the system.

Many species in this system are termed genera in the systems of other writers; and the species of those writers, are, in consequence, here termed varieties. Thus, in Dr. Cullen's Nosologia, the variola or small-pox is termed a genus, and the distinct and confluent kinds are termed species. But as the insection from the distinct kind frequently produces the confluent kind, and that of the consuent kind frequently produces the distinct; it would seem more analogous to botanical arrangement, which these nosologists profess to imitate, to call the distinct and consuent small-pox varieties than species. Because the species of plants in Botanical systems prop-

agate others fimilar to themselves; which does not uniformly occur in such vegetable productions as are termed varieties.

no analogy to each other, either in respect to their proximate cause, or to their proximate effect, though they may be somewhat similar in less essential properties; thus the thin and saline discharge from the nostrils on going into the cold air of a frosty morning, which is owing to the deficient action of the absorbent vessels of the nostrils, is one species; and the viscid mucus discharged from the secenting vessels of the same membrane, when inflamed, is another species of the same genus, Catarrhus. Which bear no analogy either in respect to their immediate cause, or to their immediate effect.

The uses of the method here offered to the public, of classing diseases according to their proximate causes, are, first, more distinctly to understand their nature by comparing their effential properties. Secondly, to facilitate the knowledge of the methods of cure; since in natural classification of diseases the species of each genus, and indeed the genera of each order, a few perhaps excepted, require the same general medical treatment. And lastly, to discover the nature and the name of any disease previously unknown to the physician; which I am persuaded will be more readily and more certainly done by this natural system, than by the artificial classifications already published.

The common names of diseases are not well adapted to any kind of classification, and least of all to this, from their proximate causes. Some of their names in common language are taken from the remote cause, as worms, stone of the bladder; others from the remote effect, as diarrhea, falivation, hydrocephalus; others from some accidental symptom of the disease, as toothach, head-ach, heart-burn; in which the pain is only a concomitant circumstance of the excess or deficiency of fibrous actions, and not the cause of them. Others again are taken from the deformity occasioned in confequence of the unnatural fibrous motions, which conftitute diseases, as tumours, eruptions, extenuations; all these therefore improperly give names to diseases; and fome difficulty is thus occasioned to the reader in endeavouring to discover to what class such disorders belong.

Another difficulty attending the names of diseases is; that one name frequently includes more than one disease; either existing at the same time or in succession. Thus the pain of the bowels from worms is caused by the increased action of the membrane from the stimulus of those animals; but the convulsions, which sometimes succeed these pains in children, are caused by the consequent volition, and belong to another class.

To discover under what class any disease should be arranged, we must first investigate the proximate cause; thus the pain of the tooth-ach is not the cause of any diseased motions, but the effect; the tooth-ach there-

fore does not belong to the class of Sensation. As the pain is caused by increased or decreased action of the membranes of the tooth, and these actions are owing to the increase or decrease of irritation, the disease is to be placed in the class of Irritation.

To discover the order it must be inquired, whether the pain be owing to increased or desective motion of the pained membrane; which is known by the concomitant heat or coldness of the part. In tooth-ach without inflammation there is generally a coldness attends the cheek in its vicinity; as may be perceived by the hand of the patient himself, compared with the opposite cheek. Hence odontalgia is found to belong to the order of decreased irritation. The genus and species must be found by inspecting the synopsis of the second order of the class of Irritation. See Class I. 2. 4. 12.

This may be further elucidated by considering the natural operation of parturition; the pain is occasioned by the increased action or distention of the vessels of the uterus, in consequence of the stimulus of the fetus; and is therefore caused by increased irritation; but the actions of the abdominal muscles in its exclusion are caused by the pain, and belong to the class of increased sensation. See Class II. 1. 1.12. Hence the difficulty of determining, under what class of diseases parturition should be arranged, consists in there being two kinds of diseased actions comprehended under one word; which have each their different proximate cause.

VOL. II.

3

In

In Sect. XXXIX. 8. 4. and in Class II. 1. 1. we have endeavoured to give names to four links of animal caufation, which conveniently apply to the claffification of diseases; thus in common nictitation, or winking with the eyes without our attention to it, the increased irritation is the proximate cause; the stimulus of the air on the dry cornea is the remote cause; the closing of the eyelid is the proximate effect; and the diffusion of tears over the eyeball is the remote effect. In some cases two more links of causation may be introduced; one of them may be termed the preremote cause; as the warmth or motion of the atmosphere, which causes greater exhalation from the cornea. And the other the post-remote effect; as the renewed pellucidity of the cornea; and thus fix links of causation may be expressed in words.

But if amid these remote links of animal causation any of the sour powers or faculties of the sensorium be introduced, the reasoning is not just according to the method here proposed; for these powers of the sensorium are always the proximate causes of the contractions of animal fibres; and therefore in true language cannot be termed their remote causes. From this criterion it may always be determined, whether more diseases than one are comprehended under one name; a circumstance which has much impeded the investigation of the causes, and cures of diseases.

Thus the term fever, is generally given to a collection of morbid fymptoms; which are indeed to many distinct diseases.

diseases, that sometimes appear together, and sometimes separately; hence it has no determinate meaning, except it signifies simply a quick pulse, which continues for some hours; in which sense it is here used.

In naming diseases I have endeavoured to avoid the affectation of making new compound Greek words, where others equally expressive could be procured: as a short periphrasis is easier to be understood, and less burdensome to the memory.

In the Methodus Medendi, which is marked by M. M. at the end of many of the species of diseases, the words incitantia, sorbentia, torpentia, &c. refer to the articles of the Materia Medica, explaining the operations of medicines.

The remote causes of many diseases, their periods, and many circumstances concerning them, are treated of in the preceding volume; the descriptions of many of them, which I have omitted for the sake of brevity, may be seen in the Nosologia Methodica of Sauvages, and in the Synopsis Nosologiæ of Dr. Cullen, and in the authors to which they refer.

In this arduous undertaking the author folicits the candour of the critical reader; as he cannot but foresee, that many errors will be discovered, many additional species will require to be inserted; and others to be transplanted or erased. If he could expend another forty years in the practice of medicine, he makes no doubt, but

that he could bring this work nearer perfection, and thence render it more worthy the attention of philosophers.—As it is, he is induced to hope, that some advantages will be derived from it to the science of medicine, and consequent utility to the public, and leaves the completion of his plan to the industry of suture generations.

DERBY, Jan. 1, 1796.

CLASS I.

DISEASES OF IRRITATION.

ORDO I.

Increased Irritation.

GENUS I.

With increased actions of the Sanguiferous System.

THE irritability of the whole, or of part, of our system is perpetually changing; these vicissitudes of irritability and of inirritability are believed to depend on the accumulation or exhauftion of the fenforial power, as their proximate cause; and on the difference of the present stimulus, and of that which we had previously been accustomed to, as their remote cause. Thus a fmaller degree of heat produces pain and inflammation in our hands, after they have been for a time immerfed in fnow; which is owing to the accumulation of fenforial power in the moving fibres of the cutaneous vessels during their previous quiescence, when they were benumbed with cold. And we feel ourselves cold in the usual temperature of the atmosphere on coming out of a warm room; which is owing to the exhaustion of fenforial power in the moving fibres of the veffels of the skin by their previous increased activity, into which they were excited by unufual heat.

Hence the cold fits of fever are the occasion of the succeeding hot ones; and the hot fits contribute to occasion in their turn the succeeding cold ones. And though the increase of stimulus, as of heat, exercise, or distention, will produce an increased action of the stimulated fibres; in the same manner as it is produced by the increased irritability which was occasioned by a previous defect of stimulus; yet as the excesses of irritation from the stimulus of external things are more easily avoided than the deficiencies of it; the diseases of this country, except those which are the consequences of drunkenness, or of immoderate exercise, more frequently begin with torpor than with orgasin; that is, with inactivity of some parts, or of the whole of the system, and consequent coldness, than with increased activity, and consequent heat.

If the hot fit be the confequence of the cold one, it may be asked if they are proportionate to each other: it is probable that Vol. II.

they are, where no part is destroyed by the cold sit, as in mortification or death. But we have no measure to distinguish this, except the time of their duration; whereas the extent of the torpor over a greater or less part of the system, which occasions the cold sit; or of the exertion which occasions the hot one; as well as the degree of such torpor or exertion, are perhaps more material than the time of their duration. Besides this, some muscles are less liable to accumulate sensorial power during their torpor, than others, as the locomotive muscles compared with the capillary arteries; on all which accounts a long cold sit may often be followed by a short hot one.

As the torpor, with which a fit of fever commences, is fometimes owing to defect of ftimulus, as in going into the coldbath; and fometimes to a previous exhaustion of the sensorial power by the action of some violent stimulus, as after coming out of a hot room into cold air; a longer time must elapse, before there can be a sufficient accumulation of sensorial power to produce a hot fit in one case than in the other. Because in the latter case the quantity of sensorial power previously expended

must be supplied, before an accumulation can begin.

The cold paroxysm commences, when the torpor of a part becomes so great, and its motions in consequence so slow or feeble, as not to excite the sensorial power of association; which in health contributes to move the rest of the system, which is in the sensorial power of irritation of the saccumulation of the sensorial power of irritation of the part first affected, either so as to counteract its deficient stimulus, or its previous waste of sensorial power; and it becomes general by the accumulation of the fensorial power of association; which is excited by the renovated actions of the part first affected; or becomes so great as to overbalance the deficient excitement of it. On all these accounts the hot sit cannot be supposed to bear any proportion to the cold one in length of time, though the latter may be the consequence of the former. See Suppl. I. 16. 8.

SPECIES.

1. Febris irritativa. Irritative fever. This is the fynocha of fome writers, it is attended with ftrong pulfe without inflamation; and in this circumftance differs from the febris inirritativa of Clafs I. 2. 1. 1. which is attended with weak pulfe without inflammation. The increased frequency of the pulfation of the heart and arteries constitutes fever; during the cold fit these pulfations are always weak, as the energy of action is then decreased throughout the whole fystem; and therefore the gener-

al arterial strength cannot be determined by the touch, till the cold part of the paroxysm ceases. This determination is sometimes attended with difficulty; as strong and weak are only comparative ae grees of the greater or less resistance of the pulsation of the artery to the compression of the singer. But the greater or less frequency of the pulsations assorbed a collateral evidence in those cases, where the degree of strength is not very distinguishable, which may assist our judgment concerning it. Since a moderately strong pulse, when the patient is in a recumbent posture, and not hurried in mind, seldom exceeds 120 strokes in a minute; whereas a weak one often exceeds 130 in a recumbent posture, and 150 in an erect one, in those severs, which are termed nervous or putrid. See Sect. XII. 1. 4.

The increased frequency of the pulsation of the heart and arteries, as it is occasioned either by excess or defect of stimulus, or of sensorial power, exists both in the cold and hot sits of sever; but when the cold sit ceases, and the pulse becomes strong and full as well as quick, in consequence of the increased irritability of the heart and arteries, it constitutes the irritative sever, or synocha. It is attended with considerable heat during the paroxysim, and generally terminates in a quarter of a lunation, without any disturbance of the faculties of the mind. See Class IV. 1. 1.8.

M. M. Venefection. Emetics. Cathartics. Cool the patient in the hot fit, and warm him in the cold one. Rest. Torpentia.

2. Ebrietas. Drunkenness. By the stimulus of wine or opium the whole arterial system, as well as every other part of the moving system, is excited into increased action. All these secretions, and with them the production of sensorial power itself in the brain, seem to be for a time increased, with an additional quantity of heat, and of pleasurable sensation. See Sect. XXI. on this subject. This explains, why at the commencement of the warm paroxysm of some severs the patient is in greater spirits, or vivacity; because, as in drunkenness, the irritative motions are all increased, and a greater production of sensation is the confequence, which, when in a certain degree, is pleasurable, as in the diurnal sever of weak people. Sect. XXXVI. 3. 1.

3. Hamorrhagia arteriofa. Arterial hamorrhage. Bleeding with a quick, strong, and full pulse. The hamorrhages from the lungs, and from the nose, are the most frequent of these; but it sometimes happens, that a small artery but half divided, or the puncture of a leech, will continue to bleed pertinaciously.

M. M. Venesection. Cathartic with calomel. Divide the wounded artery. Bind sponge on the puncture. If coffee or

charcoal, internally? If air, with less oxygen?

4. Hamoptes arteriofa. Spitting of arterial blood. Blood spit

up from the lungs is florid, because it has just been exposed to the influence of the air in its passage through the extremities of the pulmonary artery; it is frothy, from the admixture of air with it in the bronchia. The patients frequently vomit at the same time from the disagreeable titillation of blood about the sauces; and are thence liable to believe, that the blood is ejected from the stomach.

Sometimes an hæmoptoe for feveral fucceffive days returns in gouty persons without danger, and seems to supply the place of the gouty paroxysms. Is not the liver always diseased previous to the hæmoptoe, as in several other hæmorrhages? See Class

I. 2. I. 9.

M. M. Venefection, a purge, a blifter, diluents, torpentia; and afterwards forbentia, as the bark, the acid of vitriol, and opium. An emetic is faid to stop a pulmonary hæmorrhage, which it may effect, as sickness decreases the circulation, as is very evident in the great sickness sometimes produced by too large

a dose of digitalis purpurea.

Dr. Rush says, a table-spoonful or two of common salt is successful in hæmoptoe; this may be owing to its stimulating the absorbent systems, both the lymphatic, and the venous. Should the patient respire air with less oxygen? or be made sick by whirling round in a chair suspended by a rope? One immersion in cold water, or a sudden sprinkling all over with cold water, would probably stop a pulmonary hæmorrhage. See Sect. XXVII. I.

5. Hamorrhagia narium. Episfaxis. Bleeding at the nose in elderly subjects most frequently attends those, whose livers are enlarged or inflamed by the too frequent use of fermented liquors.

In boys it occurs perhaps fimply from redundancy of blood; and in young girls fometimes precedes the approach of the catamenia; and then it shews a disposition contrary to chlorosis;

which arises from a deficiency of red blood.

M. M. It is stopped by plunging the head into cold water, with powdered falt hashily dissolved in it; or sometimes by lint strewed over with wheat slower put up the nostrils; or by a solution of steel in brandy applied to the vessel by means of lint. The cure in other respects as in hæmoptoe; when the bleeding recurs at certain periods, after venesection, and evacuation by calomel, and a blister, the bark and steel must be given, as in intermittent severs. See Section XXVII. 1.

The tincture of digitalis given in proper quantities, as 30 drops from a two-ounce phial every fix hours for two or three or four doses, is probably an efficacious medicine. See Dr. Ferriar's Treatise on Digitalis. He stopped active hæmorrhages by the exhibition of digitalis.

ORDO.

ORDO I.

Increased Irritation.

GENIIS IL

With increased Actions of the Secerning System.

These are always attended with increase of partial or of gengeral heat; for the secreted sluids are not simply separated from the blood, but are new combinations; as they did not previously exist as such in the blood vessels. But all new combinations give out heat chemically; hence the origin of animal heat, which is always increased in proportion to the secretion of the part affected, or to the general quantity of the secretions. Nevertheless there is reason to believe, that as we have a sense purposely to distinguish the presence of greater or less quantities of heat, as mentioned in Sect. XIV. 6. so we may have certain minute glands for the secretion of this sluid, as the brain is believed to secrete the sensorial power, which would more easily account for the instantaneous production of the blush of shame, and of anger. This subject deserves further investigation.

SPECIES.

r. Calor febrilis. The heat in fevers arises from the increase of some secretion, either of the natural sluids, as in irritative severs; or of new sluids, as in insectious severs; or of new vessels, as in inflammatory severs. The pain of heat is a consequence of the increased extension or contraction of the sibres

exposed to so great a stimulus. See Class I. 1.5.6.

2. Rubor febrilis. Febrile redness. When the cold fit of sever terminates, and the pulsations of the heart and arteries become strong as well as quick from the increase of their irritability after their late quiescence, the blood is impelled forwards into the fine extremities of the arteries, and the anastamosing capillaries, quicker than the extremities of the veins can absorb and return it to the heart. Hence the pulse at the wrist becomes full, as well as quick and strong, and the skin glows with arterial blood, and the veins become empty and less visible.

In elderly people the force of the heart and arteries becomes lefs, while the abforbent power of the veins remains the fame; whence the capillary vessels part with the blood, as soon as it is received, and the skin in consequence becomes paler; it is also

probable,

probable, that in more advanced life some of the finer branches of the arteries coalefce, and become impervious, and thus add to

the opacity of the skin.

3. Sudor calidus. Warm fweat may be divided into four varieties, according to its remote causes. First, the perspirable matter is secreted in as great quantity during the hot fit of fever. as towards the end of it, when the fweat is feen upon the skin. But during the hot fit the cutaneous absorbents act also with increated energy, and the exhalation is likewife increased by the greater heat of the fkin; and hence it does not appear in drops on the furface, but is in part re-absorbed, and in part diffipated in the atmosphere. But as the mouths of the cutaneous absorbents are exposed to the cool air or bedclothes; whilst those of the capitlary glands, which fecrete the perspirable matter, are exposed to the warmth of the circulating blood; the former, as foon as the fever-fit begins to decline, lofe their increased action first, and hence the abtorption of the sweat is diminished, whilst the increased secretion of it continues for some hours afterwards.

which occasions it to stand in drops upon the skin.

As the skin becomes cooler, the evaporation of the perspirable matter becomes lefs, as well as the abforption of it. And hence the diffipation of aqueous fluid from the body, and the confequent thirst, are perhaps greater during the hot fit, than during the subsequent sweat. For the sweats do not occur, according to Dr. Alexander's experiments, till the skin is cooled from 112 to 108 degrees of heat; that is, till the paroxysm begins to decline. From this it appears, that the fweats are not critical to the hot fit, any more than the hot fit can be called critical to the cold one; but fimply, that they are the natural consequence of the decline of the hot fit, commencing with the decreased action of the absorbent system, and the decreased evaporation from the skin. And from hence it may be concluded, that a fever-fit is not in general an effort of nature to restore health, as Sydenham confidered it, but a necessary consequence of the previous torpor; and that the causes of fevers would be less detrimental, if the fever itself could be prevented from existing; as appears in the cool treatment of the small-pox.

It must be noted that the profuse sweats on the skin are more frequent at the decline of fever-fits than the copious urine, or loofe flools, which are mentioned below; as the cutaneous abforbents, being exposed to the cool air, lose their increased action fooner than the urinary or intestinal absorbents; which open into the warm cavities of the bladder and intestines; but which are nevertheless often affected by their sympathy with the cutaneous abforbents. Hence few fevers terminate without a

moisture

moisture of the skin; whence arose the fatal practice of forcing sweats by the external warmth of air or bed-clothes in severs; for external warmth increases the action of the cutaneous capillaries more than that of the other secenting vessels; because the latter are habituated to 98 degrees of heat, the internal warmth of the body; whereas the cutaneous capillaries being nearer the surface are habitually kept cooler by the contact of the external air. Sweats thus produced by heat in confined rooms are still more detrimental; as the air becomes then not only deprived of a part of its oxygene by frequent respiration, but is loaded with animal essure as well as with moisture, tilt it can receive no more; and in consequence, while the cutaneous secretion stands upon the skin in drops for want of exhalation, the lungs are exposed to an insalubrious atmosphere.

I do not deny, that fweating may be fo managed as to be ferviceable in preventing the return of the cold paroxyifm of fevers; like the warm bath, or any other permanent stimulus, as wine, or opium, or the bark. For this purpose it should be continued till past the time of the expected cold fit, supported by moderate doses of wine-whey, with spirit of hartshorn, and moderate degrees of warmth. Its falutary effect, when thus managed, was probably one cause of its having been so much attended to; and the fetid smell, which when profuse is liable to accompany it, gave occasion to the belief, that the supposed material cause of the disease was thus eliminated from the circulation.

When too great external heat is applied, the fyftem is weakened by excess of action, and the torpor which causes the cold paroxysm recurs sooner and more violently. For though some stimuli, as of opium and alcohol, at the same time that they exhaust the sensorial power by promoting increase of sibrous action, may also increase the production or secretion of it in the brain, yet experience teaches us that the exhaustion far out-balances the increased production, as is evinced by the general debility, which succeeds intoxication.

In refpect to the fetor attending copious continued fweats, it is owing to the animalized part of this fluid being kept in that degree of warmth, which most favours putrefaction, and not suffered to exhale into the atmosphere. Broth, or other animal mucus, kept in similar circumstances, would in the same time acquire a putrid smell; yet has this error frequently produced miliary eruptions, and increased every kind of inflammatory or sensitive fever.

The ease, which the patient experiences during sweating, if it be not produced by much external heat, is similar to that of the warm bath; which by its stimulus applied to the cutaneous

veffels.

CLASS I. 1. 2. 3.

veffels, which are generally cooler than the internal parts of the fystem, excites them into greater action; and pleasurable sensation is the confequence of these increased actions of the vessels of the skin. From considering all these circumstances, it appears that it is not the evacuation by sweats, but the continued ftimulus, which caufes and supports those sweats, which is ferviceable in preventing the returns of fever-fits. And that fweats too long continued, or induced by too great stimulus of warmth, clothes, or medicines, greatly injure the patient by increasing inflammation, or by exhausting the fenforial power. See Class I. I. 2. 14.

Secondly, The fweats produced by exercise or labour are of the warm kind; as they originate from the increased action of the capillaries of the skin, owing to their being more powerfully stimulated by the greater velocity of the blood, and by a greater quantity of it passing through them in a given time For the blood during violent exercise is carried forwards by the action of the muscles faster in the arteries, than it can be taken up by the veins; as appears by the redness of the skin. And from the confequent sweats, it is evinced, that the secretory vessels of the skin during exercise pour out the perspirable matter faster, than the mouths of the absorbent vessels can drink it up. Which mouths are not exposed to the increased muscular action, or to the stimulus of the increased velocity and quantity of the bloods but to the cool air.

Thirdly, the increased secretion of perspirable matter occasioned by the stimulus of exteral heat belongs likewife to this place; as it is caused by the increased motions of the capillary vessels; which thus feparate from the blood more perspirable matter, than the mouths of their correspondent absorbent vessels can take up; though these also are stimulated by external heat into more energetic action. If the air be stationary, as in a small room, or bed with closed curtains, the sweat stands in drops on the skin for want of a quicker exhalation proportioned to the quicker fecretion.

A fourth variety of warm perspiration is that occasioned by stimulating drugs, of which opium and alcohol are the most powerful; and next to these the spices, volatile alkali, and neutral falts, especially sea-falt; that much of the aqueous part of the blood is diffipated by the use of these drugs, is evinced by the great thirst, which occurs a few hours after the use of them. See Art. III. 2. 1.

We may from hence understand, that the increase of this fecretion of perspirable matter by artificial means, must be followed by debility and emaciation. When this is done by taking much inuch falt, or falted meat, the fea-fcurvy is produced; which confifts in the inirritability of the bibulous terminations of the veins arifing from the capillaries; fee Class I. 2. 1. 14. The fcrofula, or inirritability of the lymphatic glands, feems also to be occasionally induced by an excess in eating falt added to food of bad nourishment. See Class I. 2. 3. 21. If an excess of perspiration is induced by warm or stimulant clothing, as by wearing slannel in contact with the skin in the summer months, a perpetual febricula is excited, both by the preventing the access of cool air to the skin, and by perpetually goading it by the numerous and hard points of the ends of the wool; which when applied to the tender skins of young children, frequently produce the red gum, as it is called; and in grown people, either an erysipelas, or a miliary eruption, attended with fever. See Class II.

Shirts made of cotton or calico stimulate the skin too much by the points of the fibres, though lefs than flannel; whence cotton handkerchiefs make the note fore by frequent use. The fibres of cotton are, I suppose, ten times shorter than those of flax, and the number of points in confequence twenty times the number; and though the manufacturers finge their calicoes on a red-hot iron cylinder, yet I have more than once feen an ervlipelas induced or increated by the stimulus of calico, as well as of flannel; and have during the last fummer prevailed on two, who were confined to their beds by fevers, and three, who were in a state of great debility, to differentiate themselves of the slannel shirts, which they had worn for some time; all of them became immediately and confiderably relieved; and found no inconvenience afterwards by discontinuing an unnecessary stimulus, which had nothing to recommend it to those patients but the frivolous fashion of the day.

The inconvenience, which weak constitutions experience from wearing flannel shirts, arises from this circumstance; that the extremities of their limbs are more liable to become cold, than the furface of the cheft and abdomen, and that hence they should in preference wear warmer stockings, shoes, and focks, or gloves. By flimulating the warmer parts of the skin into too strong and useless exertion, as by the hard points of a flannel shirt at all seafons, and by its confining the warmth of the skin too much in the fummer months, a part of the fenforial power becomes unnecessarily expended; and in weak constitutions, where there is none to spare, some other parts of the system must act with less energy; and thus I believe the extremities of feeble people become colder by the use of a flannel shirt; in stronger people, and perhaps in warmer climates, this increased coldness of the ex-Vol. II. tremities tremities may not be perceptible; as stronger persons can better bear some increased exertion, and the consequent unnecessary loss of some sensorial power; and in warmer climates the extremi-

ties may not be so liable to become cold.

Analogous to this I remember to have seen an inoculated child about fix years old, whose bosom and face, at the beginning of the eruptive sever, were of a fiery red colour, and exceedingly hot to the touch; and whose seet were at the same time pale, and cold to the touch. When on exposing the bosom and face to colder air with the seet only slightly covered, the colour of the former in a few minutes became nearly natural, with little excess of tangible heat, and at the same time the seet became as warm as natural.

Whence I conclude, that all unnecessary increase of stimuli, as of warm clothing, wine, and opium, is more injurious to seeble constitutions than to robust ones; and that such stimuli alone are salutary to weak persons, as increase those actions of the system, which are immediately necessary to life and health, as the class of medicines termed forbentia, as peruvian bark, and other bitters, and very small quantities of steel, as these seem to increase the activity of the absorbent system, both of the lymphatic and venous ones, and thus supply more nutrition, with all its salutary consequences. And that the use of these forbentia, as well as of the occasional use of warmer clothing, wine, and opium, should be discontinued, as soon as the system can acquire the natural habit of acting with sufficient energy without them. See Article II. 2. 2. 1. of the Materia Medica.

The increase of perspiration by heat either of clothes, or of sire, contributes much to emaciate the body; as is well known to jockeys, who, when they are a stone or two too heavy for riding, find the quickest way to lessen their weight is by sweating themselves between blankets in a warm room; but this likewise is a practice by no means to be recommended, as it weakens the system by the excess of so general a stimulus, brings on a premature old age, and shortens the span of life; as may be further deduced from the quick maturity, and shortness of the lives, of the inhabitants of Hindostan, and other tropical climates.

When the heat of the body in weak patients in fevers is increafed by the stimulus of the points of slannel, a greater consequent debility succeeds, than when it is produced by the warmth of fire; as in the former the heat is in part owing to the increased activity of the skin, and consequent expenditure of sensorial power; whereas in the latter case it is in part owing to the insux of

the fluid matter of heat.

So the warmth produced by equitation, or by rubbing the body, and limbs with a fmooth brush or hand, as is done after bathing

in some parts of the East, does not expend nearly so much senforial power, as when the warmth is produced by the locomotion of the whole weight of the body by muscular action, as in
walking, or running, or swimming. Whence the warmth of a
fire is to be preferred to slannel skirts for weak people, and the
agitation of a horse so exercise on foot. And I suppose those,
who are unfortunately lost in snow, who are on foot, are liable
to perish sooner by being exhausted by their muscular exercious;
and might frequently preserve themselves by lying on the ground,
and covering themselves with snow, before they were too much
exhausted by fatigue. See Botan. Garden, Vol. II. the note on
Bezometz.

M. Buffon made a curious experiment to flew this circumstance. He took a numerous brood of the butterflies of filkworms, fome hundreds of which left their eggs on the same day and hour; these he divided into two parcels; and placing one parcel in the fouth window, and the other in the north window of his house, he observed, that those in the colder situation lived many days longer than those in the warmer one. From these observations it appears, that the wearing of slannel clothing next the skin, which is now so much in fashion, however useful it may be in the winter to those, who have cold extremities, bad digestions, or habitual coughs, must greatly debilitate them, if worn in the warm months, producing severs, eruptions, and premature old age. See Sect. XXXVII. 5. Class I. 1. 2. 14. Art. III. 2. 1.

4. Urina uberior colorata. Copious coloured urine. Towards the end of fever-fits a large quantity of high coloured urine is voided, the kidneys continuing to act strongly, after the increased action of the absorbents of the bladder is somewhat diminished. If the absorbents continue also to act strongly, the urine is higher coloured, and fo loaded as to deposit, when cool, an earthy fediment, erroneously thought to be the material cause of the difease; but is simply owing to the secretion of the kidneys being great from their increased action; and the thinner parts of it being absorbed by the increased action of the lymphatics, which are spread very thick on the neck of the bladder; for the urine, as well as perhaps all the other fecreted fluids, is produced from the kidneys in a very dilute state; as appears in those, who from the stimulus of a stone, or other cause, evacuate their urine too frequently; which is then pale from its not having remained in the bladder long enough for the more aqueous part to have been re-absorbed. The general use of this urinary abforption to the animal occonomy is evinced from the urinary bladders of fish, which would otherwise be unnecessary. High coloured urine in large quantity shews only, that the secreting veffels of the kidneys, and the abforbents of the bladder, have afted with greater energy. When there is much earthy fediment, it shews, that the abforbents have afted proportionally stronger, and have confequently left the urine in a less dilute state. In this urine the transparent fediment or cloud is mucous; the opaque fediment is probably coagulable lymph from the blood changed by an animal or chemical process. The floating scum is oil. The angular concretions to the sides of the pot, formed as the urine cools, is microcosmic salt. Does the adhesive blue matter on the sides of the glass, or the blue circle on it at the edge of the upper surface of the urine, consist of Prussian blue?

5. Diarrhæa calida. Warm diarrhæa. This species may be divided into three varieties, deduced from their remote causes, under the names of diarrhæa febrilis, diarrhæa crapulosa, and diarrhæa infantum. The febrile diarrhæa appears at the end of fever-fits, and is erroneously called critical, like the copious urine, and the sweats; whereas it arises from the increased action of those secential canal (as the liver, pancreas, and mucous glands,) continuing longer than the increased action of the intestinal absorbents. In this diarrhæa there is no appearance of curdled chyle in the stools, as occurs in cholera. I. 3. 1. 5.

The diarrhea crapulofa, or diarrhea from indigestion, occurs when too great a quantity of food or liquid has been taken; which not being completely digested, stimulates the intestines like any other extraneous acrid material; and thus produces an increase of the secretions into them of mucus, pancreatic juice, and bile. When the contents of the bowels are still more stimulant, as when drastic purges, or very putrescent diet, have been

taken, a cholera is induced. See Sect. XXIX. 4.

The diarrhæa infantum, or diarrhæa of infants, is generally owing to too great acidity in their bowels. Milk is found curdled in the stomachs of all animals, old as well as young, and even of carnivorous ones, as of hawks. (Spallanzani.) And it is the gastric juice of the calf, which is employed to curdle milk in the process of making cheese. Milk is the natural food for children, and must curdle in their stomachs previous to digestion; and as this curdling of the milk destroys a part of the acid juices of the stomach, there is no reason for discontinuing the use of it, though it is occasionally ejected in a curdled state. A child of a week old, which had been taken from the breaft of its dying mother, and had by fome uncommon error been fuffered to take no food but water-gruel, became fick and griped in twenty-four hours, and was convulfed on the fecond day, and died on the third! When all young quadrupeds, as well as children.

children, have this natural food of milk prepared for them, the analogy is fo ltrong in favour of its falubrity, that a perfor fhould have powerful testimony indeed of its disagreeing before he advises the discontinuance of the use of it to young children in health, and much more so in sickness. The farmers lose many of their calves, which are brought up by gruel, or gruel and old milk; and among the poor children of Derby, who are thus fed, hundreds are starved into the scrosula, and either perish,

or live in a state of wretched debility.

When young children are brought up without a breast, they should for the first two months have no food but new milk; fince the addition of any kind of bread or flour is liable to ferment, and produce too much acidity; as appears by the confequent diarrhœa with green dejections and gripes; the colour is owing to a mixture of acid with the natural quantity of bile, and the pain to its stimulus. And they should never be fed as they lie upon their backs, as in that posture they are necessitated to fwallow all that is put into their mouths; but when they are fed, as they are fitting up, or raifed up, when they have had enough, they can permit the rest to run out of their mouths. This circumstance is of great importance to the health of those children, who are reared by the spoon, since if too much food is given them, indigestion, and gripes, and diarrhoea, are the consequence; and if too little, they become emaciated; and of this exact quantity their own palates judge the best.

M. M. In this last case of the diarrheea of children, the food should be new milk, which by curdling destroys part of the acid, which coagulates it. Chalk about four grains every six hours, with one drop of spirit of hartshorn, and half a drop of laudanum. But a blister about the size of a shilling is of the greatest service by restoring the power of digestion. See Article III. 2.

1. in the Materia Medica.

6. Salivatio calida. Warm falivation. Increased secretion of faliva. This may be effected either by stimulating the mouth of the gland by mercury taken internally; or by stimulating the excretory duct of the gland by pyrethrum, or tobacco; or simply by the movement of the muscles, which lie over the gland, as in massicating any tasteless substance, as a lock of wool, or massic.

In about the middle of nervous fevers a great spitting of saliva sometimes occurs, which has been thought critical; but as it commues sometimes two or even three weeks without the relief of the patient, it may be concluded to arise from some accidental circumstance, perhaps not unsimilar to the hysteric ptyalisms mentioned in Class I. 3. 2. 2. See Sect. XXIV.

M. M. Cool

M. M. Cool air, diluents, warm bath, evacuations.

7. Catarrhus calidus. Warm eatarth. Confifts in an increased secretion of mucus from the nostrils without inflammation. This disease, which is called a cold in the head, is frequently produced by cold air acting for some time on the membranes, which line the nostrils, as it passes to the lungs in respiration. Whence a torpor of the action of the mucous glands is first introduced, as in Class I. 2. 3. 3. and an orgasm or increased action succeeds in consequence. Afterwards this orgasm and torpor are liable to alternate with each other for some time like the cold and hot fits of ague, attended with deficient or exuberant secretion of mucus in the nostrils.

At other times it arifes from reverfe sympathy with some extensive parts of the skin, which have been exposed too long to cold, as of the head, or feet. In confequence of the torpor of these cutaneous capillaries those of the mucous membrane of the nostrils act with greater energy by reverse sympathy; and thence fecrete more mucus from the blood. At the same time the abforbents, acting also with greater energy by their reverse sympathy with these of some distant part of the skin, absorb the thinner parts of the mucus more hastily; whence the mucus is both thicker and in greater quantity. Other curious circumstances attend this difease; the membrane becomes at times so thickened by its increased action in secreting the mucus, that the patient cannot breathe through his nostrils. In this fituation if he warms his whole kin fuddenly by fire or bed-clothes, or by drinking warm tea, the increased action of the membrane ceases by its reverse sympathy with the skin; or by the retraction of the fenforial power to other parts of the fystem; and the patient can breathe again through the noftrils. The fame fometimes occurs for a time on going into the cold air by the deduction of heat from the mucous membrane, and its confequent inactivity or torpor. Similar to this when the face and breaft have been very hot and red, previous to the eruption of the small-pox by inoculation, and that even when exposed to cool air, I have obferved the feet have been cold; till on covering them with warm flannel, as the feet have become warm, the face has cooled. See Sect. XXXV. 1. 3. Class II. 1. 3. 5. IV. 2. 2. 10. IV. 1. 1. 5.

M. M. Evacuations, abstinence, oil externally on the note,

warm diluent fluids, warm shoes, warm night-cap.

8. Empelloratio calida. Warm expectoration confifts of the increased sceretion of mucus from the membrane, which lines the bronchiæ, or air-cells of the lungs, without inflammation. This increased mucus is ejected by the action of coughing, and

is called a cold, and resembles the catarrh of the preceding article; with which it is frequently combined.

M. M. Inhaling the steam of warm water, evacuations, warm

bath, afterwards opium, forbentia.

9. Exfudatio pone aures. A discharge behind the ears. This chiefly affects children, and is a morbid fecretion; as appears from its fetor; for if it was owing to defect of absorption, it would be faline, and not fetid; if a morbid action has continued a confiderable time, it should not be stopped too suddenly; fince in that case some other morbid action is liable to succeed in its flead. Thus children are believed to have had colics, or even convulsions, consequent to the too sudden healing of these morbid effusions behind their ears. The rationale of this is to be explained from a medical fact, which I have frequently observed; and that is, that a blifter on the back greatly strengthens the power of digestion, and removes the heart-burn in adults, and green stools in children. The stimulus of the blister produces fensation in the veffels of the skin; with this additional sensorial power these vessels act more strongly; and with these the vesfels of the internal membranes of the stomach and bowels act with greater energy from their direct fympathy with them. Now the acrid discharge behind the ears of children produces fensation on that part of the skin, and so far acts as a small blis-When this is fuddenly stopped, a debility of the digestive power of the stomach succeeds from the want of this accustomed stimulus, with flatulency, green stools, gripes, and sometimes consequent convulsions. See Class II. 1. 5. 6. and II. 1. 4. 6.

M. M. If the matter be abforbed, and produce fwelling of the lymphatics of the neck, it should be cured as soon as possible by dusting the part with white lead, cerusia, in very fine powder; and to prevent any ill consequence an issue should be kept for about a month in the arm; or a purgative medicine should be taken every other day for three or four times, which should consist of a grain of calomel, and three or four grains of rhubarb, and as much chalk. If there be no appearance of absorption, it is better only to keep the parts clean by washing them with warm water morning and evening; or putting fuller's earth on them; especially till the time of toothing is past. The timea, or scald head, and a seprous eruption, which often appears behind

the ears, are different diseases.

10. Gonorrhea calida. Warm gleet. Increased discharge of mucus from the urethra or prostrate gland without venereal defire, or venereal infestion. See Class I. 2. 3. 8.

M. M. Cantharides, balfams, rhubarb, blifter on perinæum,

cold bath, injections of metallic falts, flannel shirt, change of the form of the accustomed chair or saddle of the patient.

11. Fluor albus calidus. Warm fluor albus. Increased secretion of mucus in the vagina or uterus without venereal desire of venereal infection. It is distinguished from the fluor albus frigidus by the increased sense of warmth in the part, and by the greater opacity or spissificate of the material discharged; as the thinner parts are re-absorbed by the increased action of the absorbents, along with the saline part, whence no smarting or excoriation attends it.

M. M. Mucilage, as ifinglass, hartshorn jelly, gum arabic. Ten grains of rhubarb every night. Calico or slannel shift, opi-

um, balfams. See Class I. 2. 3. 7.

12. Hamorrhois alba. White piles. An increased discharge of mucus from the rectum frequently mistaken for matter; is said to continue a few weeks, and recur like the bleeding piles; and to obey lunar influence. See Class I. 2. 1. 6.

M. M. Abstinence from vinous spirit. Balsam of copaiva. Spice swallowed in large fragments, as ten or sisteen black pepper-corns cut in half, and taken after dinner and supper. Wara's paste, consisting of black pepper and the powdered root of He-

lenium Enula.

13. Serum e reficatorio. Discharge from a blister. The excretory ducts of glands terminate in membranes, and are endued with great irritability, and many of them with sensibility; the latter perhaps in consequence of their facility of being excitable into great action; instances of this are the terminations of the gall-duct in the duodenum, and of the fallwary and lachrymal glands in the mouth and eye; which produce a greater secretion of their adapted sluids, when the ends of their excretory ducts are stimulated.

The external skin consists of the excretory ducts of the capillaries, with the mouths of the absorbents; when these are stimulated by the application of cantharides, or by a slice of the fresh root of bryonia alba bound on it, the capillary glands pour an increased quantity of sluid upon the skin by their increased action; and the absorbent vessels imbibe a greater quantity of the more sluid and saline part of it; whence a thick mucous or serious sluid is deposited between the skin and cuticle.

14. Perspiratio fætida. Fetid perspiration. The uses of the perspirable matter are to keep the skin soft and pliant, for the purposes of its easier flexibility during the activity of our limbs in locomotion, and for the preservation of the accuracy of the sense of touch, which is diffused under the whole surface of it to guard us against the injuries of external bodies; in the same

manner as the fecretion of tears is defigned to preferve the cornea of the eye moift, and in consequence transparent; yet has this cutaneous mucus been believed by many to be an excrement; and I know not how many fanciful theories have been built on its supposed obstruction. Such as the origin of catarrhs,

coughs, inflammations, eryfipelas, and herpes.

To all these it may be sufficient to answer, that the ancient Grecians oiled themselves all over; that some nations have painted themselves all over, as the Picts of this island; that the Hottentots smear themselves all over with grease. And lastly, that many of our own heads at this day are covered with the slour of wheat and the fat of hogs, according to the tyranny of a filthy and wasteful sashion, and all this without inconvenience. To this must be added the strict analogy between the use of the perspirable matter and the mucous sluids, which are poured for similar purposes upon all the internal membranes of the body; and besides its being in its natural state inodorous; which is not so with the other excretions of seces, or of urine.

The quantity of perspirable matter being greater than that of the excrementitious matters voided by stool and urine, has been used as an argument in favour of its being an excrement; the force of which I do not see: but can readily understand, that there must of necessity be a great exhalation of a sluid which is diffused over the whole external surface of the warm skin, and perhaps warmer lungs, for the purpose of keeping them moist and pliant, and which is perpetually renewed as it evaporates; but, if it be conceived to be an excrement, there seems to have been no necessity for its quantity being so great.

The evaporation of this great quantity of fluid, secreted on the furface of the skin and lungs, must carry off much heat from the body; and as both this secretion and consequent evaporation will be in proportion to the activity of the curaneous vessels, and the heat occasioned by their increased secretion, it would seem, that this evaporation of perspirable matter is the cause which preserves the animal body at the uniform degree of heat of 98; in the same manner as the evaporation of boiling water preserves

it at 212 degrees of Farenheit's scale.

The peculiar use of the perspirable matter in preserving the membranes moist, which line the air-pipes of the lungs, appears from the curious discovery of Dr. Priestley, that the oxygen of the atmosphere will pass through moist animal membranes, but not through dry ones, so that if the membranes of the trachea were to become dry, the animal must as immediately perish as if he was to breath azotic gas alone. See Sect. XXVIII. 2. of the preceding volume.

Vol. II. E In

In some constitutions the perspirable matter of the lungs acquires a difagreeable odour; in others the axilla, and in others the feet, emit difgustful effluvia; like the secretions of those glands, which have been called odoriferæ; as those, which contain the castor in the beaver, and those within the rectum of dogs, the mucus of which has been supposed to guard them against the great costiveness, which they are liable to in hot fummers; and which has been thought to occasion canine madness, but which, like their white excrement, is more probably owing to the deficient fecretion of bile. Whether these odoriferous particles attend the perspirable matter in consequence of the increased action of the capillary glands, and properly be called excrementitious; that is, whether any thing is eliminated, which could be hurtful if retained; or whether they may only contain some of the effential oil of the animal; like the fmell, which adheres to one's hand on stroking the hides of fome dogs; or like the effluvia, which is left upon the ground, from the feet of men and other creatures; and is perceptible by the nicer organs of the dogs, which hunt them, may admit of

Add to this, that some parts of the skin are liable to more profuse perspiration than other parts without possessing any fetid fcent, as the skin of the face, on any more violent exercise. This feems to have been observed very early in the history of mankind, as it was faid, that our first parents should earn their bread by the sweat of their brow. Why this circumstance does not attend other animals is a curious inquiry. Mankind foon learned to cover their bodies, except their faces, with clothes; when the face, by being more frequently exposed to greater variations of heat and cold, acquired greater irritability, or fensibility, or affociability, and thus has become more excitable into greater action by the stimulus of exercise, or by that of food, or by the variolus infection, than other parts of the skin, as spoken of in Class IV. 1. 2. 12; which also appears by its sympathy with difeases of the liver or stomach by sensitive affociations, as in the gutta rosea. From all these analogous facts the profuse sweat, which exudes from the face on exercise, does not appear to be an excrementitious fluid, but fimply the consequence of more violent action of the cutaneous or perspirative glands.

M. M. Wash the parts twice a day with soap and water; with lime water; cover the feet with oiled filk focks, which must be washed night and morning. Cover them with charcoal recently made red hot, and beaten into fine powder and fifted, as foon as cold, and kept well corked in a bottle, to be washed

off and renewed twice a day. Internally rhubarb grains vi. or viii. every night, fo as to procure a ftool or two extraordinary every day, and thus by increasing one evacuation to decrease another. Cool drefs, diluting liquids?

15. Crines novi. New hairs. The black points on the faces of some people confist of mucus, which is become viscid, and which adheres in the excretory ducts of the glands of the skin; as described in Class I. 2. 2. 9. and which may be pressed out by the fingers, and refembles little worms. Similar to this would feem the fabrication of filk and of cobweb, by the filkworm and spider; which is a secreted matter pressed through holes, which are the excretory ducts of glands. And it is probable, that the production of hair on many parts of the body, and at different periods of life, may be effected by a fimilar process; and more especially as every hair may be considered as a slender flexible horn, and is an appendage of the skin. See Sect. XXXIX. 3. 2. Now as there is a fensitive fympathy between the glands, which fecrete the femen, and the throat, as appears in the mumps; fee Hydrophobia, Class IV. 1. 2. 7. and Parotitis, Class IV. 1. 2. 19. the growth of the beard at puberty feems to be caused by the greater action of the cutaneous glands about the chin and pubes in consequence of their sympathy with those of the testes. But this does not occur to the female sex at their time of puberty, because the sensitive sympathy in them seems to exist between the submaxillary glands, and the pectoral ones; which fecrete the milk, and afford pleafure both by that fecretion, and by the erection of the mammulæ, or nipples; and by delivering the milk into the mouth of the child; this fenfitive fympathy of the pectoral and fubmaxillary glands in women is also observable in the Parotitis, or mumps, as above

When hairs grow on the face or arms so as to be disagreeable, they may be thus readily removed without pain or any ill consequence. Warm the ends of a pair of nippers or forceps, and stick on them a little resin, or burgundy pitch; by these means each single hair may be taken fast hold of; and if it be then plucked off slowly, it gives pain; but if plucked off suddenly, it gives no pain at all; because the vis inertime of the part of the skin, to which it adheres, is not overcome; and it is not in consequence separated from the cellular membrane under it. Some of the hairs may return, which are thus plucked off, or others may be induced to grow near them; but in a little time they may be thus safely destroyed; which is much to be preferred to the methods said to be used in Turkey

to eradicate hair; fuch as a mixture of orpiment and quick lime; or of liver of fulphur in folution; which injure the skin, if they are not very nicely managed; and the hair is liable to grow again as after shaving; or to become white, if the roots of it have been much inflamed by the causticity of the application. See Class I. 2. 2. 11. on grey hairs.

ORDO L

Increased Irritation.

GENUS III.

With increased Actions of the Absorbent System.

THESE are not attended with fo great increase of heat as in the former genus, because the fluids probably undergo less chemical change in the glands of the absorbent system; nor are the glands of the absorbent vessels so numerous or so extensive as those of the secerning ones. Yet that some heat is produced by the increased action of the absorbents appears from the greater general warmth of the skin and extremities of feeble patients after the exhibition of the peruvian bark, and other medicines of the article Sorbentia.

SPECIES.

1. Lingua arida. Dry tongue occurs in those fevers, where the expired air is warmer than natural; and happens to all those, who sleep with their mouths open; the currents of air in respiration increasing the evaporation. There is also a dryness in the mouth from the increased action of the absorbent vessels, when a floe or a crab-apple is masticated; and after the perspiration has been much increased by eating falt or spice, or after other copious fecretions; as after drunkenness, cathartics, or fever fits, the mucus of the mouth becomes viscid, and in small quantity, from the increased absorption, adhering to the tongue like a white flough. In the diabetes, where the thirst is very great, this flough adheres more pertinaciously, and becomes black or brown, being coloured after a few days by our aliment or drink. The inspissated mucus on the tongue of those, who sleep with their mouths open, is fometimes reddened as if mixed with blood, and fometimes a little blood follows the expuition of it from the fauces owing to its great adhesion. When this mucus adheres long to the papillæ of the tongue, the faliva, which it contains in its interffices, like a sponge, is liable to become putrid, and to acquire a bitter taste, like other putrid animal substances; which is generally mistaken for an indication of the presence of bile.

M. M. Warm fubacid liquids. See Class I. 2. 5. 8.

2. Fauces arida. Dry throat. The expuition of a frothy

mucus with great and perpetual hawking occurs in hydrophobia, and is very diffressing to the patient; which may be owing to the increased irritability or sensibility of the upper part of the cesophagus, which will not permit any fluid to rest on it.

It affects some people after intoxication, when the lungs remain slightly inflamed, and by the greater heat of the air in expiration the mucus becomes too hastily evaporated, and is expec-

torated with difficulty in the state of white froth.

I knew a person, who for twenty years always waked with his tongue and throat quite dry; so that he was necessitated to take a spoonful of water, as soon as he awoke; otherwise a little blood always followed the forcible expuition of the indurated mucus from his fauces. See Class II. 1. 3. 17.

M. M. Steel-springs fixed to the night-cap so as to suspend the lower jaw and keep it closed; or springs of elastic gum. Or a pot of water suspended over the bed, with a piece of list, or woollen cloth, depending from it, and held in the mouth; which will act like a syphon, and slowly supply moisture, or barley water should be frequently syringed into the mouth of the patient.

3. Nares aridi. Dry nostrils with the mucus hardening upon their internal surface, so as to cover them with a kind of skin or scale, owing to the increased action of the absorbents of this membrane; or to the too great dryness of the air, which passes into the lungs; or too great heat of it in its expiration.

When air is fo dry as to lose its transparency; as when a tremulous motion of it can be seen over corn-fields in a hot summer's day; or when a dry mist, or want of transparency of the air, is visible in very hot weather; the sense of smell is at the same time impersect from the dryness of the membrane, beneath which

it is spread.

4. Expectoratio folida. Solid expectoration. The mucus of the lungs becomes hardened by the increased absorption, so that it adheres and forms a kind of lining in the air-cells, and is sometimes spit up in the form of branching vessels, which are called polypi of the lungs. See Transact. of the College, London. There is a rattling or wheezing of the breath, but it is not at first attended with inflammation.

The Cynanche trachealis, or Croup, of Dr. Cullen, or Angina polyposa of Michaelis, if they differ from the peripneumony of infants, seem to belong to this genus. When the difficulty of respiration is great, venesection is immediately necessary, and then an emetic, and a blifter. And the child should be kept nearly upright in bed as much as may be. See Tonsillitis, Class II. 1. 3. 3. and II. 1. 2. 4.

M. M. Diluents, emetics, effence of antimony, feetid gums, onions.

onions, warm bath for half an hour every day for a month. Inhaling the steam of water, with or without volatile alkali. Soap.

5. Constipatio alvi. Costiveness from increased action of the intestinal absorbents. The feces are hardened in lumps called scybala; which are sometimes obliged to be extracted from the rectum with a kind of marrow spoon. This is said to have happened from the patient having taken much rust of iron. The mucus is also hardened so as to line the intestines, and to come away in skins, rolled up as they pass along, so as to resemble worms, for which they are frequently mistaken; and sometimes it is evacuated in still larger pieces, so as to counterfeit the form of the intestines, and has been mistaken for a portion of them. Balls of this kind, nearly as heavy as marble, and considerably hard, from two inches to five in diameter, are frequently found in the bowels of horses. Similar balls found in goats have been called Bezoar.

M. M. Cathartics. Diluents, fruit, oil, foap, fulphur, warm bath. Sprinkling with cold water, cool clothing. See Class I. 2. 4. 18.

6. Cutis arida. Dry skin. This dry skin is not attended with coldness as in the beginning of fever-fits. Where this cutaneous absorption is great, and the secreted material upon it viscid, as on the hairy scalp, the skin becomes covered with hardened mucus; which adheres so as not to be easily removed, as the scurs on the head; but is not attended with inflammation like the Tinea, or Lepra. The moisture, which appears on the skin beneath resinous or oily plasters, or which is seen to adhere to such plasters, is owing to their preventing the exhalation of the perspirable matter, and not to their increasing the production of it, as some have idly imagined.

M. M. Warm bathing, oil externally, oil-skin gloves, refin-

ous plasters. Wax.

7. Urina parca colorata. Diminished urine, which is high coloured, and deposits an earthy sediment, when cold, is owing to the great action of the urinary absorbents. See Class I. 1. 2.
4. In some dropsies the cutaneous absorbents are paralytic, as well as those opening into the cellular membrane; and hence, no moisture being acquired from the atmosphere, or from the cellular membrane, great thirst is excited; and great absorption from all parts, where the absorbents are still capable of action. Hence the urine is in very small quantity, and of deep colour, with copious sediment; and the kidneys are erroneously blamed for not doing their office; stimulant diuretic medicines are given in vain; and very frequently the unhappy patient is restrained from quenching his thirst, and dies a martyr to false theory.

M. M. Diluent

M. M. Diluent liquids, and warm bathing, are the natural cure of this fymptom; but it generally attends those dropsies, which are seldom curable; as they are owing to a paralysis both

of the cutaneous and cellular lymphatics.

8. Calculus felleus. Gall-stone. From the too hasty absorption of the thinner parts of the bile, the remainder is left too viscid, and crystallizes into lumps; which, if too large to pass, obstruct the ductus choledochus, producing pain at the pit of the stomach, and jaundice. When the indurated bile is not harder than a boiled pea, it may pass through the bile-duct with disficulty by changing its form; and thus gives those pains, which have been called spasms of the stomach; and yet these viscid lumps of bile may afterwards dissolve, and not be visible among the seces.

In two inftances I have feen from thirty to fifty gall-stones voided after taking an oil vomit as below. They were about the fize of peas, and distinguishable when dry by their being inflammable like bad wax, when put into the slame of a candle.

For other causes of jaundice, see Class I. 2. 4. 19.

M. M. Diluents, daily warm bathing. Ether mixed with yolk of egg and water. Unboiled acrid vegetables, as lettuce, cabbage, mustard, and cresses. When in violent pain, four ounces of oil of olives, or of almonds, should be swallowed; and as much more in a quarter of an hour, whether it stays or not. The patient should lie on the circumference of a large barrel, first on one side, and then on the other. Electric shocks through the gall-duct. Factitious Seltzer water made by dissolving one dram of sal foda in a pint of water; to half a pint of which made luke-warm add ten drops of marine acid; to be drunk as soon as mixed, twice a day for some months. Opium must be used to quiet the pain, if the oil does not succeed, as two grains, and another grain in half an hour if necessary. See Class IV. 2. 2. 4.

9. Calculus renis. Stone of the kidney. The pain in the loins and along the course of the ureter from a stone is attended with retraction of the testicle in men, and numbres on the inside of the thigh in women. It is distinguished from the lumbago or sciatica, as these latter are seldom attended with vomiting, and have pain on the outside of the thigh, sometimes quite down to

the ancle or heel. See Herpes and Nephritis.

Where the absorption of the thinner parts of the secretion takes place too hastily in the kidneys, the hardened mucus, and consequent calculous concretions, sometimes totally stop up the tubuli uriniferi, and no urine is secreted. Of this many die, who have drunk much vinous spirit, and some of them recover by voiding a quantity of white mucus, like chalk and water; and

others

others by voiding a great quantity of fand, or small calculi. This hardened mucus frequently becomes the nucleus of a stone in the bladder. The falts of the urine, called microcosmic salt, are often mistaken for gravel, but are distinguishable both by their angles of crystallization, their adhesion to the sides or bottom of the pot, and by their not being formed till the urine cools. Whereas the particles of gravel are generally without angles, and always drop to the bottom of the vessel, immediately as the water is voided.

Though the proximate cause of the formation of the calculous concretions of the kidneys, and of chalk-stones in the gout, and of the insoluble concretions of coagulable lymph, which are found on membranes, which have been inflamed in peripneumony, or rheumatism, consists in the two great action of the absorbent vessels of those parts; yet the remote cause in these cases is probably owing to the inflammation of the membranes; which at that time are believed to secrete a material more liable to coagulate or concrete, than they would otherwise produce by increased action alone without the production of new vessels, which constitutes inflammation. As defined in Class II. 1. 2.

The fluids fecreted from the mucous membranes of animals are of various kinds and confiftencies. Hair, filk, scales, horns, finger-nails, are owing to natural processes. Gall-stones, stones found in the intestines of horses, scurf of the skin in leprosy, stones of the kidneys and bladder, the callus from the inslamed periosteum, which unites broken bones, the calcareous cement, which repairs the injured shells of snails, the calcareous crust on the eggs of birds, the annually renewed shells of crabs, are all instances of productions from mucous membranes, afterwards in-

durated by abforption of their thinner parts.

All these concretions contain phosphoric acid, mucus, and calcareous earth in different proportions; and are probably so far analogous in respect to their component parts as well as their mode of formation. Some calcareous earth has been discovered after putrefaction in the coagulable lymph of animals. For dyce's Elements of Practice. A little calcareous earth was detected by Scheele or Bergman in the calculus of the bladder with much phosphoric acid, and a great quantity of phosphoric acid is shewn to exist in oyster-shells by their becoming luminous on exposing them a while to the sun's light after calcination; as in the experiments of Wilson. Botanic Garden, P. 1. Canto 1. 1. 182, note. The exchange of which phosphoric acid for carbonic acid, or fixed air, converts shells into lime-stone, producing mountains of marble, or calcareous strata.

Now as the hard lumps of calcareous matter, termed crabs' Vol. II.

eyes, which are found in the stomachs of those animals previous to the annual renewal of their shells, are redissolved, probably by their gastric acid, and again deposited for that purpose; may it not be concluded, that the stone of the bladder might be dissolved by the gastric juice of sish of prey, as of crabs, or pike; or of voracious young birds, as young rooks or hawks, or even of calves? Could not these experiments be tried by collecting the gastric juice by putting bits of sponge down the throats of young crows, and retracting them by a string in the manner of Spallanzani? or putting pieces of calculus down the throat of a living crow, or pike, and observing if they become digested? and lastly, could not gastric juice, if it should appear to be a solvent, be injected and borne in the bladder without injury by means of

catheters of classic refin, or caoutchouc?

M. M. Diluents. Cool drefs. Frequent change of posture. Frequent horizontal rest in the day. Bathe the loins every morning with a fponge and cold water. Aerated alkaline water internally. Abstinence from all fermented or spirituous liquors. Whatever increases perspiration injures these patients, as it disfipates the aqueous particles, which ought to dilute the urine. When the constitution begins to produce gravel, it may I believe be certainly prevented by a total abstinence from fermented or spirituous liquors; by drinking much aqueous fluids; as toast and water, tea, milk and water, lemonade; and lastly by thin clothing, and fleeping on a hardish bed, that the patient may not lie too long on one fide. See Class IV. 2. 2. 2. There is reason to believe, that the daily use of opium contributes to produce gravel in the kidneys by increasing absorption, when they are inflamed; in the fame manner as is done by fermented or spirituous liquor. See Class I. 3. 2. 11.

When the kidneys are so obstructed with gravel, that no urine paffes into the bladder; which is known by the external appearance of the lower part of the abdomen, which, when the bladder is full, feems as if contracted by a cord between the navel and the bladder; and by the tension on the region of the bladder diffinguishable by the touch; or by the introduction of the catheter; the following methods of cure are frequently successful. Venefection to fix or eight ounces, ten grains of calomel, and an infusion of senna with falts and oil, every three hours, till flools are procured. Then an emetic. After the patient has been thus evacuated, a blifter on the loins should be used; and from ten to twenty electric shocks should be passed through the kidneys, as large as can be eafily borne, once or twice a day. Along with this method the warm bath should be used for an hour once or twice a day. After repeated evacuations a clyfter, confisting

confifting of two drams of turpentine dissolved by yolk of egg, and fixty drops of tincture of opium, should be used at night, and repeated, with cathartic medicines interposed, every night, or alternate nights. Aerated solution of alkali should be taken internally, and balsam of copaiva, three or four times a day. Some of these patients recover after having made no water for nine or ten days.

If a stone sticks in the ureter with incessant vomiting ten grains of calomel must be given in small pills as above; and some hours afterwards insusion of senna and salts and oil, if it can be made to stay on the stomach. And after the purge has operated four or five times, an opiate is to be given, if the pain continues, consisting of two grains of opium. If this does not succeed, ten or twenty electric shocks through the kidney should be tried, and the purgative repeated, and afterwards the opiate. The patient should be frequently put into the warm bath for an hour at a time. Eighty or a hundred drops of laudanum given in a glyster, with two drams of turpentine, are to be preferred to the two grains given by the stomach as above, when the pain and vomiting are very urgent.

to. Calculus vesica. Stone of the bladder. The nucleus, or kernel, of these concretions is always formed in the kidney, as above described; and passing down the ureter into the bladder, is there perpetually increased by the mucus and salts secreted from the arterial system, or by the mucus of the bladder, disposed in concentric strata. The stones found in the bowels of horses are also formed on a nucleus, and consist of concentric spheres; as appears in sawing them through the middle. But as these are formed by the indurated mucus of the intestines alone without the urinary salts, it is probable a difference would

be found on their analysis.

As the stones of the bladder are of various degrees of hardness, and probably differ from each other in the proportions at least of their component parts; when a patient, who labours under this afflicting disease, voids any small bits of gravel; these should be kept in warm solutions of caustic alkali, or of mild alkali well aerated; and if they dissolve in these solutions, it would afford greater hopes, that that which remains in the bladder, might be affected by these medicines taken by the stomach, or injected into the bladder.

To prevent the increase of a stone in the bladder much diluent drink should be taken; as half a pint of water warmed to about eighty degrees, three or four times a day: which will not only prevent the growth of it, by preventing any microcosmic salts from being precipitated from the urine, and by keeping the mu-

cus suspended in it; but will also diminish the stone already formed, by softening, and washing away its surface. To this must be added cool dress, and cool bed-clothes, as directed above in the calculus renis.

When the stone is pushed against or into the neck of the bladder, great pain is produced; this may sometimes be relieved by the introduction of a bougie to push the stone back into the sundus of the bladder. Sometimes by change of posture, or by an

opiate either taken into the stomach, or by a clyster.

A dram of fal foda, or of falt of tartar, dissolved in a pint of water, and well faturated with carbonic acid (fixed air), by means of Dr. Nooth's glass apparatus, and drunk every day, or twice a day, is the most efficacious internal medicine yet discovered, which can be easily taken without any general injury to the constitution. An aerated alkaline water of this kind is fold under the name of factitious Seltzer water, by J. Schweppe, at No. 8, King's-street, Holborn, London; which I am told is better prepared than can be easily done in the usual glass-vessels, probably

by employing a greater pressure in wooden ones.

A curious account is given in a letter to Sir John Sinclair from Colonel Martin; who afferts, that, after using bougies and injections into the bladder, the passage of the urethra became less fensible to pain, and he was enabled to introduce small files (I fuppose, with their backs smooth); and that by these he gradually filed away the stone, as it lay in the neck of the bladder. When the stone did not properly present itself, he introduced warm water by injection into the bladder, and thus, by again endeavouring to discharge it, brought forward the stone to the neck of it. He used the file three times in twenty-four hours from April till October. Medical Journal, No. II. p. 121. If this process should be again attempted, perhaps the file might be introduced through a flexible canula, with a metallic hood at the internal end of the canula to cover the back of the file, fo as to prevent the friction of it against the urethra, or neck of the blad-If the urethra, by frequent trials, should become so infenfible as to admit easily the frequent introduction of a metallic canula, might not two fine steel wires properly tempered be joined at one end by a hinge, and thus introduced through the canula into the bladder; and when protruded beyond the extremity of the canula, they might open by their elasticity so as to receive the stone, and confine it against the end of the canula, by retracting them? The proper direction of the wire-springs, so as to open when they are pushed through the canula, must be previously given them. If this could be managed, a small file or borer might at the fame time be introduced through the canula,

the handles of which might confift of joints to permit them to bend in all directions, and thus the stone might be broken to pieces by a few trials; or if it was a fost or fragile stone, the retraction of the wire-bow might divide it at every trial, till it became almost reduced to powder. A little mechanical ingenuity might be necessary in the construction and use of this machinery; but I believe it not to be impracticable, since I read the above account of Colonel Martin, though I had often before thought of it with despair of its successful application.

Lithotomy is the last resource. Will the gastric juice of animals dissolve calculi? Will fermenting vegetable juices, as sweet-wort, or sugar and water in the act of sermentation with

yeast, dissolve any kind of animal concretions?

11. Calculus arthriticus. Gout-stones are formed on instamed membranes, like those of the kidneys above described, by the too hasty absorption of the thinner and saline parts of the mucus. Similar concretions have been produced in the lungs, and even in the pericardium; and it is probable, that the offssication, as it is called, of the minute arteries, which is said to attend old age, and to precede some mortifications of the extremities, may be a process of this kind.

As gout-stones lie near the surface, it is probable, that ether, frequently applied in their early state, might render them so liquid as to permit their re-absorption; which the stimulus of the

ether might at the same time encourage.

12. Rheumatisms chronicus. Chronic rheumatism. After the acute rheumatism some inspissated mucus, or material similar to chalk-stones of the gout, which was secreted on the inslamed membrane, is probably left, owing to the too hasty absorption of the thinner and faline part of it; and by lying on the fascia, which covers some of the muscles, pains them, when they move and rub against it, like any extraneous material.

The pain of the shoulder, which attends inflammations of the upper membrane of the liver, and the pains of the arms, which attend asthma dolorificum, or dropfy of the pericardium, are diftinguished from the chronic rheumatism, as in the latter the pain

only occurs on moving the affected muscles.

M. M. Warm bath, cold bath, bandage of emplastrum de minio put on tight, so as to compress the part. Cover the part with flannel. With oiled silk. Rub it with common oil frequently. With ether. A blister. A warmer climate. Venessection. A grain of calomel and a grain of opium for ten successive nights. The Peruvian bark.

13. Cicatrix vulnerum. The scar after wounds. In the healing of ulcers the matter is first thickened by increasing the

abforption

absorption in them; and then leffened, till all the matter is absorbed, which is brought by the arteries, instead of being deposed in the ulcer.

M. M. This is promoted by bandage, by the forbentia externally, as powder of bark, white lead; folution of fugar of lead. And by the forbentia internally after evacuations. See Sect.

XXXIII. 3. 2.

In those ulcers, which are made by the contact of external fire, the violent action of the fibres, which occasions the pain, is liable to continue, after the external heat is withdrawn. This should be relieved by external cold, as of snow, falt and water recently mixed, ether, or spirits of wine, suffered to evaporate on the part.

The cicatrix of an ulcer generally proceeds from the edges of it; but in large ones frequently from the middle, or commences in feveral places at the fame time; which probably con-

tributes to the unevenness of large scars.

14. Cornea objuscatio. Opacity of the cornea. There are few people, who have passed the middle of life, who have not at some time suffered some slight scratches or injuries of the cornea, which by not healing with a perfectly smooth surface, occasion some refractions of light, which may be conveniently seen in the sollowing manner: fill a tea-saucer with cream and tea, or with milk, and holding it to your lips, as if going to drink it, the imperfections of the cornea will appear like lines or blotches on the surface of the sluid, with a less white appearance than that surface. Those blemishes of the eye are distinguished from the musicae volitantes described in Class I. 2. 5. 3. by their being invariably seen at any time, when you look for them.

Ulcers may frequently be feen on the cornea after ophthalmy, like little pits or indentations beneath the furface of it; in this case no external application should be used, lest the fear should be lest uneven; but the cure should be confined to the internal use of thirty grains of bark twice a day, and from five to ten drops of laudanum at night, with five grains of rhubarb, if

necessary.

After ulcers of the cornea, which have been large, the inequalities and opacity of the cicatrix obscure the fight: in this case, could not a small piece of the cornea be cut out by a kind of trephine about the fize of a thick bristle, or a small crow-quill, and would it not heal with a transparent fear? This experiment is worth trying, and might be done by a piece of hollow steel wire with a sharp edge, through which might be introduced a printed steel screw; the screw to be introduced through the opaque cornea to hold it up, and press it against the cutting edge

of the hollow wire or cylinder; if the scar should heal without losing its transparency, many blind people might be made to see tolerably well by this slight and not painful operation. An experiment I wish strongly to recommend to some ingenious sur-

geon or oculift.

Or it may be attempted by pressing one end of a small canula on the centre of the cornea, and passing down it a bit of luna cornea, fixed in the end of a smaller canula, and thus introduced: the eye may be held steady by passing a thread by means of a small curved needle through a part of the tunica adjunctiva, which may be held by an assistant, or by pressing on it the end of the canula as above, which might have a slat circular rim round its extremity for that purpose.

CLASS I. I. A. I.

ORDO I.

Increased Irritations

GENUS IV.

With increased Actions of other Cavities and Membranes.

SPECIES.

1. Niclitatio irritativa. Winking of the eyes is performed every minute without our attention, for the purpose of cleaning and moistening the eye-ball; as further spoken of in Class II. I. 1. 8. When the cornea becomes too dry, it becomes at the same time less transparent; which is owing to the pores of it being then too large, so that the particles of light are refracted by the edges of each pore, instead of passing through it; in the same manner as light is refracted by passing near the edge of a knife. When these pores are filled with water, the cornea becomes again transparent. This want of transparency of the cornea is visible sometimes in dying people, owing to their inirritability, and confequent neglect of nictitation.

The increase of transparency by filling the pores with fluid is feen by foaking white paper in oil; which from an opaque body becomes very transparent, and accounts for a curious atmospheric phenomenon; when there exists a dry mist in a morning so as to render distant objects less distinct, it is a fign of a dry day; when distant objects are seen very distinct, it is a sign of rain. See Botan. Garden, Part I. add. note xxv. The particles of air are probably larger than those of water, as water will pass through leather and paper, which will confine air, hence when the atmosphere is much deprived of moisture, the pores of the dry air are fo large, that the rays of light are refracted by their edges instead of passing through them. But when as much moisture is added as can be perfectly diffolved, the air becomes transparent; and opaque again, when a part of this moisture collects into small spherules previous to its precipitation. This also accounts for the want of transparency of the air, which is seen in tremulous motions over corn-fields on hot fummer-days, or over brick-kilns, after the flame is extinguished, while the furnace still remains hot.

2. Deglutitio irritativa. The deglutition of our faliva is performed frequently without our attention, and is then an irritative action in confequence of the stimulus of it in the mouth. Or perhaps

perhaps fometimes for the purpose of disfusing a part of it over the dry membranes of the fauces and pharynx; in the same manner as tears are diffused over the cornea of the eye by the act of nicitation to clean or moisten it.

3. Respiratio et Tussis irritativa. In the acts of respiration and of coughing there is an increased motion of the air-cells of the lungs owing to some stimulating cause, as described above in Class I. 1. 2. 8. and I. 1. 3. 4. and which are frequently performed without our attention or consciousness, and are then irritative actions: and thus differ from those described in Class II. 1. 1. 2. and 5. To these increased actions of the air-cells are superadded those of the intercostal muscles and diaphragm by irritative affociation. When any unnatural stimulus acts so violently on the organs of respiration as to induce pain, the sensorial power of fensation becomes added to that of irritation, and inflammation of the membranes of them is a general confequence.

4. Exclusio bilis. The exclusion of the bile from the gall-bladder, and its derivation into the duodenum, is an irritative action in consequence of the stimulus of the aliment on the extremity of the biliary duct, which terminates in the intestine. The increafed fecretion of tears is occasioned in a similar manner by any stimulating material in the eyes; which affects the excretory ducts of the lachrymal glands. A pain of the external membrane of the eye fometimes attends any unufual stimulus of it, then the sensorial power of sensation becomes added to that of irritation,

and a superficial inflammation is induced.

5. Dentitio. Toothing. The pain of toothing often begins much earlier than is suspected; and is liable to produce convulfions; which are fometimes relieved, when the gum fwells, and becomes inflamed; at other times a diarrhoea supervenes, which is generally esteemed a favourable circumstance, and seems to prevent the convultions by supplying another means of relieving the pain of dentition by irritative exertion; and a confequent temporary exhaustion of sensorial power. See Class I. 1. 2. 5. Sect. XXXV. 2. 1.

The convultions from toothing generally commence long before the appearance of the teeth; but as the two middle incilors of the lower jaw generally appear first, and then those of the upper, it is advisable to lance the gums over these longitudinally in respect to the jaw-bones, and quite down to the periodteum, and through it.

As the convulsions attending the commencement of toothing are not only dangerous to life in their greatest degree, but are liable to induce stupor or insensibility by their continuance even in a lefs degree, the most efficacious means should be used to cure them.

Vol. II. M. M. Lance M. M. Lance the gum of the expected teeth quite through the periofteum longitudinally. Venefection by the lancet or by two or three leeches. One grain of calomel as a purge. Tincture of jalap, five or fix drops in water every three hours till it purges, to be repeated daily. After evacuations a small blister on the back or behind the ears. And lastly, two or three drops of laudanum according to the age of the child. Warm bath.

See Class III. 1. 1. 5. and 6. 6. Priapismus chronicus. I have seen two cases, where an erection of the penis, as hard as horn, continued two or three weeks without any venereal defires, but not without some pain; the easiest attitude of the patients was lying upon their backs with their knees up. At length the corpus cavernofum urethræ became fost, and in another day or two the whole subsided. In one of them a bougie was introduced, hoping to remove some bit of gravel from the caput gallinaginis, camphor, warm bathing, opium, lime-water, cold afpersion, bleeding in the veins of the penis, were tried in vain. One of them had been a free drinker, had much gutta rofacea on his face, and died fuddenly a few months after his recovery from this complaint. Was it a paralysis of the terminations of the veins, which absorb the blood from the tumid penis? or from the stimulus of indurated semenin the feminal veffels? In the latter case some venereal defires should have attended. Class III. 1. 2. 16.

The priapismus, which occurs to vigorous people in a morning before they awake, has been called the fignum falutis, or banner of health, and is occasioned by the increase of our irritability or fensibility during sleep, as explained in Sect. XVIII. 15.

7. Distentio mammularum. The distention of the nipples of lactescent women is at first owing to the stimulus of the milk. See Sect. XIV. 8. and Sect. XVI. 5. See Class II. 1. 7. 10.

8. Descensus uteri. This is a very frequent complaint after bad labours, the fundus uteri becomes inverted and descends

like the prolapfus ani.

M. M. All the usual pessaries are very inconvenient and ineffectual. A piece of fost sponge about two inches diameter introduced into the vagina gives great ease to these patients, and supports the uterus; it should have a string put through it to retract it by.

There are also peffaries now made of elastic gum, which are said to be easily worn, and to be convenient, from their having

a perforation in their centre.

9. Prolapfus ani. The lower part of the rectum becomes inverted, and descends after every stool chiefly in children; and thus stimulates the sphincter and like any other extraneous body.

M. M. It

M. M. It should be dusted over with very fine powder of gum fandarach, and then replaced. Astringent fomentations; as an infusion of oakbark, or a slight solution of alum. Hori-

zontal rest frequently in the day.

10. Lumbricus. Round worm. The round worm is sufpected in children when the belly is tumid, and the countenance bloated and pale, with swelling of the upper lip. The generation of these worms is promoted by the too dilute state of the bile, as is evident in the suke-worm found in the biliary ducts and substance of the liver in sheep; and in water-rats, in the livers of which last animals they were lately detected in large numbers by Dr. Capelle. Transactions of the college at Philadelphia, v. i.

Now as the dilute state of the bile depends on the desiciency of the absorption of its thinner parts, it appears, that the tumid belly, and bloated countenance, and swelled upper lip, are concomitant circumstances attending the general inactivity of the absorbent system; which is therefore to be escened the remote

cause of the generation of worms.

The simplicity of the structure of worms probably enables them to exist in more various temperatures of heat; and their being endued with life prevents them from being destroyed by digestion in the stomach, probably in the same manner as the powers of life prevent the fermentation and putrefaction of the stomach itself. Hence I conclude, that worms are originally taken into our alimentary canal from without; as I believe similar worms of all kinds are to be found out of the body.

M. M. The round worm is destroyed by a cathartic with four or fix grains of calomel; and afterwards by giving fix or eight grains of filings of iron twice a day for a fortnight. See Hepatis tumor, Class I. 2. 3. 9. As worms are liable to come away in fevers, whether of the hectic or putrid kind, could they be removed by purulent matter, or rotten egg, or putrid slesh, since in those fevers from the enseebled action of the intestines

the fæces become highly putrid.

The sharp spiculæ or hairs, which are sound on the pods of cowhage, struolobium siliqua hirsuta, have been recommended in worm-cases, and said to destroy them by mechanical puncture; the late Mr. Power of Polesworth, assured me, he had had great success with this medicine and gave about six or eight grains in a bolus three or four times on one day, with a brisk cathartic on the next day. Some have recommended chopped hair or bristles for this purpose. There are numerous sharp spiculæ in the fruit of the wild rose, which might be worth trying it this disease.

disease, and the hairs on full grown hairy caterpillars, if the animal be laid on the hand, especially between the singers, are liable to stick in the skin, and to produce slight inflammation and itching, and might also be worth trying in worm-cases. But it is afferted in M. Vaillant's Travels in Africa, that when these infects seed on poisonous plants, they become themselves so venomous, that the natives collect a juice from them, with which when putrid they smear their war weapons to poison them.

Tape-worm confifts of a chain of animals extending from the stomach to the anus. See Sect. XXXIX. 2. 3. It irequently exists in cats, rats, and geefe, and probably in many

other animals.

The worms of this genus posses a wonderful power of retaining life. Two of them, which were voided by a pointer dog in consequence of violent purgatives, each of which were feveral feet in length, had boiling water poured on them in a basin; which seemed not much to inconvenience them. When the water was cool, they were taken out and put into gin or whiskey of the strongest kind, in which their life and activity continued unimpaired; and they were at length killed by adding to the spirit a quantity of corrosive sublimate. Medic. Comment.

for 1791, p. 370.

The tape-worm is cured by an amalgama of tin and quickfilver, fuch as is used on the back of looking-glasses; an ounce should be taken every two hours, till a pound is taken; and then a brifk cathartic of Glauber's falt two ounces, and common falt one ounce, diffolved in two wine pints of water, half a pint to be taken every hour till it purges. The worm extends from the stomach to the anus, and the amalgama tears it from the intestine by mechanical preffure, acting upon it the whole way. Electric shocks through the duodenum greatly affift the operation. Large doses of tin in powder. Iron filings in large doses. The powder of fernroot feems to be of no use, as recommended by M. Nousslier. This worm, as well as the lumbricus or round-worm, is fometimes brought up by vomiting; when either of these worms is in the stomach it gives a tickling sensation about the fauces, which parts fympathize with the cardia ventriculi. See Annals of Medicine, 1797. Give an emetic of tartarized antimony, or of vitriol of zinc.

12. Ascarides. Thread worms. These worms are said to be more frequent in some parts of this kingdom than in others, as near the sens of Lincolnshire. Do they escape from the body and become slies, like the bott-worm in horses? Do they crawl from one child to another in the same bed? Are they acquired from slies or worms, which are seen in putrid necessary houses, as

these worms as well as the tape-worms, are probably acquired from without? this may account for their re-appearance a few weeks or months after they have been destroyed; or can this

happen from the eggs or parts of them remaining?

Ascarides appear to be of two kinds, the common small one like a thread; which has a very sharp head, as appears in the microscope; and which is so tender, that the cold air soon renders it motionless; and a larger kind above an inch long, and nearly as thick as a very small crow-quill, and which is very hard in respect to its texture, and very tenacious of life. One of these last was brought to me, and was immediately immersed in a strong solution of sugar of lead, and lived in it a very long time without

apparent inconvenience.

M. M. Ascarides are said to be weakened by twenty grains of cinnabar and five of rhubarb taken every night, but not to be cured by this process. As these worms are found only in the rectum, variety of clysters have been recommended. A clyster confisting of one eighth or one fourth of an ounce of succorrine aloes in powder boiled in a pint of milk or of gruel, till it is diffolved, and injected once a week for many weeks, I believe has fometimes effected a cure. I was informed of a case, where solutions of mercurial ointment were used as a clyster every night for a month without fuccess. Clysters of Harrowgate water are recommended, either of the natural, or of the factitious, as described below, which might have a greater proportion of liver of fulphur in it. As the cold air foon destroys them, after they are voided, could clysters of iced water be used with advantage? or of spirit of wine and water? or of ether and water? Might not a piece of candle, about an inch long, or two fuch pieces, fmeared with mercurial ointment, and introduced into the anus at night, or twice a day, be effectual by compressing their nidus, as well as by the poison of the mercury?

The clysters should be large in quantity, that they may pass high in the rectum, as two drams of tobacco boiled a minute in a pint of water. Or perhaps what might be still more efficacious and less inconvenient, the smoke of tobacco injected by a proper apparatus every night, or alternate nights, for fix or eight weeks. This was long since recommended, I think, by Mr. Turner of Liverpool; and the reason it has not succeeded, I believe to have been owing to the imperfections of the joints of the common apparatus for injecting the smoke of tobacco, so that it did not pass into the intestine, though it was supposed to do so, as I once observed. The smoke should be received from the apparatus into a large bladder; and it may then be certainly injected like the common clyster with sufficient force; otherwise

oiled

oiled leathers should be nicely put round the joints of the machine; and a wet cloth round the injecting pipe to prevent the return of the smoke by the sides of it. Clysters of carbonated hydrogen gas, or of other factitious airs, might be tried; or of

the hairs of filiqua hirfuta.

Harrowgate water taken into the stomach, so as to induce six or seven stools every morning, for sour or six weeks, is perhaps the most efficacious method in common use. A factitious Harrowgate water may be made probably of greater essicacy than the natural, by dissolving one ounce of marine salt, (called bay salt) and half an ounce of magnesia Glauber's salt, (called Epsom salt, or bitter purging salt) in twenty-eight ounces of water. A quarter or half a pint of this is to be taken every hour, or two hours in the morning, till it operates, with a tea-spoonful of a solution of liver of sulphur, which is to be made by putting an ounce of hepar sulphuris into half a pint of water. See Class IV. 1, 2, 0.

13. Dracunculus. A thin worm brought from the coast of Guinea. It is found in the interstices of the muscles, and is many yards long; it makes a small ulcer; which is cured by extracting an inch of the worm a day, and wrapping the extracted part slowly round a bit of tobacco-pipe till next day, so as not to break it. I have twice seen long worms, like a thick horse hair, in water in July in this country, which appeared hard and

jointed.

14. Morpiones. Crab-lice. The excrement of this animal

stains the linen, and appears like diluted blood.

M. M. Spirit of wine. Mercurial ointment, shaving the part. Oil destroys other insects, if they be quite covered with it, as the ticks on dogs, and would probably therefore destroy these. Its manner of operation is by stopping up or filling their spiracula, or breathing pores; a few drops of oil poured on a wasp, so to cover it, destroy it in a few seconds.

15. Pediculi. Lice. There is faid to be a disease, in which these animals are propagated in indestructible numbers, so as to

destroy the patient.

M. M. Cleanliness, mercurial ointment, stavis acriain powder, or the tincture of it in spirit of wine. Spirit of wine alone. Path of oil?

ORDO I.

Increased Irritation.

GENUS V.

With increased Actions of the Organs of Sense.

SPECIES:

1. Vifus acrior. Acuter fight. There have been instances of people, who could see better in the gloom of the evening, than in the stronger light of the day; like owls, and bats, and many quadrupeds, and slying insects. When the eye is instanced, great light becomes eminently painful, owing to the increased irritative motions of the retina, and the consequent increased sensation. Thus when the eye is dazzled with sudden light, the pain is not owing to the motion of the iris; for it is the contraction of the iris, which relieves the pain from sudden light; but to the too violent contractions of the moving sibres, which constitute the extremities of the optic nerve.

2. Auditus acrior. The irritative ideas of hearing are so increased in energy as to excite our attention. This happens in some diseases of the epileptic kind, and in some severs. Hence the whispering of the currents of air in a room, the respiration of the company, and noises before unperceived, become trouble-some; and sounds louder than usual, or unexpected, produce

starting, and convulsions.

M. M. Put oil of almonds into the ears. Stop the meatus auditorius with cotton wool. Set the feet of the patient's bed

on cushions, or suspend it by cords from the ceiling.

3. Olfactus acrior. The irritative ideas of smell from the increased action of the olfactive nerve excite our attention. Hence common odours are disagreeable; and are perceived from variety of objects, which were before thought inodorous. These are commonly believed to be hallucinations of the sense.

M. M. Snuff starch up the nostrils.

4. Gustus acrior. The irritative ideas of taste, as of our own saliva, and even of the atmospheric air, excite our attention; and common tastes are disagreeably strong.

M. M. Water. Mucilage. Vegetable acids. Scrape the

tongue clean. Rub it with a fage-leaf and vinegar.

5. Taetus acrior. The irritative ideas of the nerves of touch

CLASS I. 1. 5. 6.

excite our attention : hence our own pressure on the parts, we

rest upon, becomes uneasy with universal foreness.

M. M. Soft feather-bed. Combed wool put under the patients, which rolls under them, as they turn, and thus prevents their friction against the sheets. Drawers of fost leather. Plasters of cerate with calamy.

6. Sensus caloris acrior. Acuter sense of heat occurs in some difeases, and that even when the perceptible heat does not appear greater than natural to the hand of another person. See Class I. 1. 2. See Sect. XIV. 8. All the above increased actions of our organs of sense separately or jointly accompany some fevers, and fome epileptic difeases; the patients complaining of the perception of the least light, noises in their ears, bad smells in the room, and bad tastes in their mouths, with foreness, numbress, and other uneafy feels, and with difagreeable fenfations of general or partial heat.

7. Sensus extensionis acrior. Acuter sense of extension. The fense of extension was spoken of in Sect. XIV. 7. and XXXII. 4. The defect of diffention in the arterial fystem is accompanied with faintness; and its excess with fensations of fulness, or weight, or pressure. This however refers only to the vascular muscles, which are distended by their appropriated fluids; but

the longitudinal muscles are also affected by different quantities of extension, and become violently painful by the excess of it.

These pains of muscles and of membranes are generally divided into acute and dull pains. The former are generally owing to increase of extension, as in pricking the skin with a needle; and the latter generally to defect of extension, as in cold head-aches; but if the edge of a knife, or point of a pin, be gradually pressed against the fibres of muscles or membranes, there would feem to be three states or stages of this extension of the fibres; which have acquired names according to the degree or kind of fensation produced by the extension of them; these are 1. titillation or tickling; 2. itching; and the 2. finarting, as described below. See Sect. XIV. 9.

8. Titillatio. Tickling is a pleafurable pain of the fense of extension above mentioned, and therefore excites laughter; as described in Sect. XXXIV. 1. 4. The tickling of the nostrils, which precedes the efforts of fneezing, is owing to the increased irritation occasioned by external stimulus; and is attended with a pleasurable sensation in consequence of the increased action of the part. When this action is exerted in a greater degree, the fensation becomes painful, and the convulsion of sneezing enfues; as the pain in tickling the foles of the feet of children is

relieved by laughter.

In

A lady after a bruise on her nose by a fall was affected with incessant fneezing, and relieved by fnushing starch up her nostrils. Perpetual fneezings in the meafles, and in catarrhs from cold, are owing to the stimulus of the saline part of the mucous esfufion on the membrane of the nostrils. See Class II. 1. 1. 2.

o. Pruritus. Itching feems to be a greater degree of titillation, and to be owing to the stimulus of some acrid material, as the matter of the itch; or of the herpes on the scrotum, and about the anus; or from those universal eruptions, which attend some elderly people, who have drunk much vinous spirit. It occurs also, when inflammations are declining, as in the healing of blifters, or in the cure of ophthalmia, as the action of the velfels is yet fo great as to produce fenfation; which, like the titillations that occasion laughter, is perpetually changing from pleafure to pain.

When the natural efforts of scratching do not relieve the pain of itching, it fometimes increases so as to induce convulsions and madness. As in the furor uterinus, and satyriasis, and in the fphincter ani and fcrotum. See Class II. 1. 4. 14. IV. 2. 2. 6.

M. M. Warm bath. Fomentation. Alcohol externally. Poultice. Oiled filk. Mercurial ointments on finall furfaces at once. See Class II. 1. 4. 12. Solutions of lead on small furfaces at once.

10. Dolor urens. Smarting follows the edge of a knife in making a wound, and feems to be owing to the diffention of a part of a fibre, till it breaks. A fmarting of the skin is liable to affect the fcars left by herpes or fhingles; and the callous parts of the bottoms of the feet; and around the bases of corns on the toes; and frequently extends after sciatica along the outside of the thigh, and of the leg, and part of the foot. All these may be owing to the stimulus of extension, by blood or ferum being forced into veffels nearly coalefced.

M. M. Emplastrum de minio put like a bandage on the part. Warm fomentation. Oil and camphor rubbed on the part. Oilfilk covering. A blifter on the part. Ether, or alcohol, fuffer-

ed to evaporate on the part.

11. Consternatio. Surprise. As our eyes acquaint us at the fame time with less than half of the objects, which furround us, we have learned to confide much in the organ of hearing to warn us of approaching dangers. Hence it happens, that it any found strikes us, which we cannot immediately account for, our fears are instantly alarmed. Thus in great debility of body, the loud clapping of a door, or the fall of a fire-shovel, produces alarm, and fometimes even convulsions; the same occurs from unexpected fights, and in the dark from unexpected objects of touch. VOL. II.

H

In these cases the irritability is less than natural, though it is erroneously supposed to be greater; and the mind is busied in exciting a train of ideas inattentive to external objects; when this train of ideas is differered by any unexpected stimulus, furprife is excited; as explained in Sect. XVII. 3. 7. and XVIII. 17. then as the fensibility in these cases is greater, fear becomes fuperadded to the furprife; and convulsions in confequence of

the pain of fear. See Sect. XIX. 2.

The proximate cause of surprise is the increased irritation induced by some violent stimulus, which dissevers our usual trains of ideas; but in difeases of inirritability the frequent starting or furprise from sounds not uncommon, but rather louder than usual, as the clapping of a door, shews, that the attention of the patient to a train of fensitive ideas was previously stronger than natural, and indicates an incipient delirium; which is therefore

worth attending to in febrile difeafes.

ORDO II.

Decreased Irritation.

GENUS I.

With decreased Action of the Sanguiferous System.

THE reader should be here apprized, that the words strength and debility, when applied to animal motions, may properly express the quantity of resistance such motions may overcome; but that, when they are applied to mean the susceptibility or insusceptibility of animal sibres to motion, they become metaphorical terms; as in Sect. XII. 2. 1. and would be better expressed by

the words activity and inactivity.

There are three fources of animal inactivity; first, the defect of the natural quantity of stimulus on those fibres, which have been accustomed to perpetual stimulus; as the arterial and secerning systems. When their accustomed stimulus is for a while intermitted, as when snow is applied to the skin of the hands, an accumulation of sensorial power is produced; and then a degree of stimulus, as of heat, somewhat greater than that at present applied, though much less than the natural quantity, excites the vessels of the skin into violent action. We must observe, that a deficiency of stimulus in those sibres, which are not subject to perpetual stimulus, as the locomotive muscles, is not succeeded by accumulation of sensorial power; these therefore are more liable to become permanently inactive after a diminution of stimulus; as in strokes of the palfy, this may be called inactivity from defect of stimulus.

2. A fecond fource of animal inactivity exists, when the senforial power in any part of the system has been previously exhausted by violent stimuli; as the eyes after long exposure to great light; or the stomach, to repeated spirituous potation; this may be termed inactivity from exhaustion of sensorial pow-

er. See Sect. XII. 2. 1.

3. But there is a third fource of inactivity owing to the deficient production of fenforial power in the brain; and hence stimuli stronger than natural are required to produce the accustomed motions of the arterial system; in this case there is no accumulation of sensorial power produced; as in the inactivity owing to defect of stimulus; nor any previous exhaustion of it, as in the inactivity owing to excess of stimulus.

This third kind of inactivity causes many of the diseases of this genus; which are therefore in general to be remedied by fuch medicines as promote a greater production of fenforial power in the brain; as the incitantia, confifting of wine, beer and opium, in small repeated quantities; and secondly of such as simply stimulate the arterial and glandular system into their natural actions; as small repeated blisters, spices and essential oils. And lastly the forbentia, which contribute to supply the more permanent strength of the system, by promoting the absorption of nourishment from the stomach and intestines; and of the superstuous sluid, which attends the secretions.

SPECIES.

nitior, or nervous fever of some writers; it is attended with weak pulse without inflammation, or symptoms of putridity, as they have been called. When the production of sensorial power in the brain is less than usual, the pulse becomes quick as well as weak; and the heart sometimes trembles like the limbs of old age, or of enseebled drunkards; and when this force of the contractions of the heart and arteries is diminished, the blood is pushed on with less energy, as well as in less quantity, and thence its stimulus on their sides is diminished in a duplicate ratio. In compressions of the brain, as in apoplexy, the pulse becomes slower and suller; for in that disease, as in natural sleep, the irritative motions of the heart and arteries are not diminished, volition alone is suspended or destroyed.

If the absorption of the terminations of the veins is not equally impaired with the force of the heart and arteries, the blood is taken up by the veins the instant it arrives at their extremities; the capillary vessels are left empty, and there is less resistance to the current of the blood from the arteries; hence the pulse becomes empty, as well as weak and quick; the veins of the skin are fuller than the arteries of it; and its appearance becomes

pale, bluish, and shrunk. See Class II. 1. 3. 1.

When this pulse persists many hours, it constitutes the febris inirritativa, or typhus, or nervous sever, of some writers; it is attended with little heat, the urine is generally of a natural colour, though in less quantity; with great proftration of strength, and much disturbance of the faculties of the mind. Its immediate cause seems to be a deficient secretion of the sensorial power from the inaction of the brain; hence almost the whole of the sensorial power is expended in the performance of the motions necessary to life, and little of it can be spared for the voluntary actions of the locomotive muscles, or organs of sense, see Class I. 2. 5. 3. Its more remote cause may be from a paraly-

fis or death of some other part of the body; as of the spleen, when a tumour is selt on the lest side, as in some intermittents; or of the kidneys, when the urine continues pale and in small quantity. Does the revivescence of these affected parts, or their terpor, recurring at intervals, form the paroxysms of these severes? and their permanent revivescence establish the cure? See Class IV. 2. I. 19.

The inirritative fever differs from the puerperal and from the hectic fever, by the permanent inactivity of the stomach, which in this disease admits of no solid nutriment. See Class II. 1. 6.

16. and Suppl. I. 12.

M. M. Wine and opium in small quantities repeated every three hours alternately; small repeated blisters; warm but fresh air; forbentia; nutrientia; transfusion of blood. Small electric shocks passed through the brain in all directions. Oxygene air?

2. Parefis inivitativa. Inirritative debility. A defective action of the irritative motions without increase of the frequency of the pulse. It continues three or four weeks like a fever, and then either terminates in health, or the patient finks into one kind of apoplexy, and perishes. Many symptoms, which attend inirritative fevers, accompany this disease, as cold hands and seet at periodic times, scurf on the tongue, want of appetite, muddy urine, with pains of the head, and sometimes vertigo, and vomiting.

This difease differs from the inirritative sever by the pulse not being more frequent than in health. The want of appetite and of digestion is a principal symptom, and probably is the cause of the universal debility, which may be occasioned by the want of nourishment. The vertigo is a symptom of inirritability, as shewn in Class IV. 1. 2. 6. the muddy urine is owing to increased absorption from the bladder in consequence of the diminished cutaneous and cellular absorption, as in anasarca, explained in Sect. XXIX. 5. 1. and is therefore a consequence of the inirritability of that part of the system; the foul tongue is owing to an increased absorption of the thinner part of the mucus in consequence of the general desciency of sluid, which should be absorbed by the skin and stomach. The sickness is owing to decreased action of the stomach, which is probably the primary disease, and is connected with the vertigo.

M. M. An emetic. Calomel, grains iv. once or twice. Then a blifter. Peruvian bark. Valerian. Columbo. Steel. Opium and wine in fmall quantities, repeated alternately every three

hours. Small electric percussions through the stomach.

3. Somnus interruptus. Interrupted fleep. In fome fevers, where the inirritability is very great, when the patient falls afleep,

the pulse in a few minutes becomes irregular, and the patient awakes in great disorder, and fear of dying, refusing to sleep again from the terror of this uneasy sensation. In this extreme debility there is reason to believe, that some voluntary power during our waking hours is employed to aid the irritative stimuli in carrying on the circulation of the blood through the lungs; in the same manner as we use voluntary exertions, when we listen to weak sounds, or wish to view an object by a small light; in sleep volition is suspended, and the descient irritation alone is not sufficient to carry on the pulmonary circulation. This explanation seems the most probable one, because in cases of apoplexy the irritative motions of the arterial system do not seem to be impaired, nor in common sleep. See Incubus III. 2. 1. 13.

M. M. Opium in very small doses, as three drops of laudanum. A person should watch the patient, and awaken him frequently; or he should measure the time between slumber and slumber by a stop-watch, and awaken the patient a little before he would otherwise awake; or he should keep his singer on the pulse, and should forcibly awaken him, as soon as it becomes irregular, before the disorder of the circulation becomes so great as to disturb him. See Class I. 2. 1. 9. and Sect. XXVII. 2.

4. Syncope. Fainting confifts in the decreased action of the arterial system; which is sometimes occasioned by defect of the stimulus of distention, as after venefection, or tapping for the dropsy. At other times it arises from great emotions of the mind, as in sudden joy or grief. In these cases the whole sensorial power is exerted on these interesting ideas, and becomes exhausted. Thus during great surprise or fear the heart stops for a time, and then proceeds with throbbing and agitation; and sometimes the vital motions become so deranged, as never to recover their natural successive action; as when children have been frightened into convulsions. See Sect. XII. 7. 1.

Miss —, a young lady of Stafford, in travelling in a chaife was so affected by seeing the fall of a horse and postillion, in going down a hill, though the carriage was not overturned, that the fainted away, and then became convulsed, and never spoke afterwards; though she lived about three days in successive con-

vulfions and ftupor.

5. Hamorrhagia venefa. A bleeding from the capillaries arifing from defect of venous abforption, as in fome of those fevers commonly termed putrid. When the blood stagnates in the cellular membrane, it produces petechiæ from this torpor or paralyfis of the absorbent mouths of the veins. It must be observed, that those people who have diseased livers, are more liable to this kind of hæmorrhages, as well as to the hæmorrhagia arteriosa;

the former, because patients with diseased livers are more subject to paralytic complaints in general, as to hemiplegia, and to dropfy, which is a paralysis of the lymphatics; and the latter is probably owing to the delay of the circulation in the vena porta by the torpor of this hepatic vessel, when the liver is not much enlarged; and to its pressure on the vena cava, when it is much enlarged.

I have feen two elderly men, and one middle aged woman, all of whom had drunk too much fermented or fpirituous liquors, and had been for fome months gradually finking, were feized with a ceafeless hæmorrhage from their mouths, and from every part of the skin, where they happened to feratch themselves, which continued some days till they died. See Sect. XXVII. 2.

M. M. Vitriolic acid, opium, steel, bark. Sponge bound on the part. Steel dissolved in spirit of wine externally. Flour.

6. Hamorrhois cruenta. In the bleeding piles the capillary veffels of the rectum become distended and painful from the defect of the venous absorption of the part, and at length burst; or the mucous glands are so dilated as to give a passage to the blood; it is said to observe lunar periods.

M. M. Venefection, poultices, cathartics, spice, cold bath, and forbentia. External compression by applying lint, sponge, or cotton. Internal compression by applying a bit of candle smeared with mercurial ointment. Strangulate the tumid piles with a filk string. Cut them off. See Sect. XXVII. 2.

Mrs. — had for twelve or fifteen years, at intervals of a year or less, a bleeding from the rectum without pain; which however stopped spontaneously after she became weakened, or by the use of injections of brandy and water. Lately the bleeding continued above two months, in the quantity of many ounces a day, till she became pale and feeble to an alarming degree. Injections of folutions of lead, of bark and falt of steel, and of turpentine, with fome internal aftringents, and opiates, were used in vain. An injection of the fmoke of tobacco, with ten grains of opium mixed with the tobacco, was used, but without effect the two first times on account of the imperfection of the machine; on the third time it produced great fickness, and vertigo, and nearly a fainting fit; from which time the blood entirely stopped. Was this owing to a fungous excrescence in the rectum; or to a blood-vessel being burst from the difficulty of the blood passing through the vena porta from some hepatic obstruction, and which had continued to bleed fo long? Was it stopped at last by the fainting fit? or by the stimulus of the tobacco?

7. Hamorrhagia renum. Hamorrhage from the kidneys, when attended with no pain, is owing to defect of venous absorption in

the kidney. When attended with pain on motion, it is owing to a bit of gravel in the ureter or pelvis of the kidney; which is a much more frequent difease than the former. See Sect. XXVII. 1.

M. M. 1. Venefection in fmall quantity, calomel, bark, fleel, an opiate; cold immersion up to the navel, the upper part of the body being kept clothed. Neville-Holt water. 2. Alcalized water aerated. Much diluent liquids. Cool drefs. Cool bed-room.

Cows are much subject to bloody urine, called foul water by the farmers; in this disease about fixty grains of opium with or without as much rust of iron, given twice a day, in a ball mixed with slour and water, or dissolved in warm water, or warm ale, are, I believe, an essectious remedy, to which however should be added about two quarts of barley or oats twice a day, and a cover

at night, if the weather be cold.

8. Hamorrhagia hepatis. Hæmorrhage from the liver. It fometimes happens in those, who have the gutta rosea, or paralytic affections owing to diseased livers induced by the potation of fermented liquors, that a great discharge of black viscid blood occasionally comes away by stool, and sometimes by vomiting: this the ancients called melancholia, black bile. If it was bile, a small quantity of it would become yellow or green on dilution with warm water, which was not the case in one experiment which I tried; it must remain some time in the intestines from its black colour, when it passes downwards, and probably comes from the bile-ducts, and is often a fatal symptom. When it is evacuated by vomiting it is less dangerous, because it shews greater remaining irritability of the intestinal canal, and is sometimes salutary to those who have diseased livers.

Two elderly men, who had loft their appetite for animal food, which is always a dangerous fymptom, when it occurs to chose who have drank too much fermented liquor, observed, that they parted with black stools. One of them also had the mucus of his nostrils occasionally stained with blood. The black stools appeared evidently to consist of the coagulum of blood, sometimes without other seces. After a few weeks, they both sunder this discharge, which I supposed to proceed from the liver, as it never appeared florid in any part of it. See Section

XXVII. 2.

M. M. An emetic. Rhubarb, steel, wine, bark, opium.

o. Hamoptoe venosa. Venous hamoptoe frequently attends the beginning of the hereditary consumptions of dark-eyed people; and in others, whose lungs have too little irritability. These spittings of blood are generally in very small quantity, as a teaspoonful;

spoonful; and return at first periodically, as about once a month; and are lefs dangerous in the female than in the male fex; as in the former they are often relieved by the natural periods of the menses. Many of these patients are attacked with this pulmonary hæmorrhage in their first sleep; because in seeble people the power of volition is necessary, besides that of irritation, to carry on respiration perfectly; but, as volition is sufpended during fleep, a part of the blood is delayed in the veifels of the lungs, and in confequence effused, and the patient awakes from the disagreeable sensation. See Class I. 2. 1. 3. II. 1. 6. 6. III. 2. 1. 10. and Sect. XXVII. 2.

M. M. Wake the patient every two or three hours by an alarum clock. Give half a grain of opium at going to bed, or twice a day. Onions, garlic, flight chalybeates. Iffues. Leeches applied once a fortnight or month to the hemorrhoidal veins to produce a new habit. Emetics after each period of hæmoptoe, to promote expectoration, and dislodge any esfused blood, which might by remaining in the lungs produce ulcers by its putridity. A hard bed, to prevent too found fleep. A periodical emetic or cathartic once a fortnight.

10. Palpitatio cordis. The palpitation of the heart frequently attends the hæmoptoe above mentioned; and confifts in an ineffectual exertion of the heart to pulh forwards its contents in due time, and with due force. The remote cause is frequently fome impediment to the general circulation; as the torpor of the capillaries in cold paroxyims of fever, or great adhesions of the lungs. At other times it arises from the debility of the action of the heart owing to the deficient tensorial power of irritation or of affociation, as at the approach of death.

In both these cases of weak exertion the heart feels large to the touch, as it does not completely empty itself at each contraction; and on that account contracts more frequently, as described in Sect. XXXII. 2. 2. Another kind of palpitation may fometimes arise from the retrograde motions of the heart, as in fear. See

Class I. 3. 1. 2. and IV. 3. 1. 6.

11. Menorrhagia. Continued flow of the catamenia. The monthly effusion of blood from the uterus or vagina is owing to a torpor of the veins of those membranes in consequence of the defect of venereal stimulus; and in this respect resembles the mucus discharged in the periodical venereal orgasm of the temale quadrupeds, which are fecluded from the males. The menorrhagia, or continued flow of this discharge, is owing to a continued defect of the venous absorption of the membranes of the uterus or vagina. See Class IV. 2. 4. 7.

M. M. Venefection in small quantity. A cathartic. Then VOL. II opium opium, a grain every night. Steel. Bark. A blifter. Topi-

cal afpertion with cold water, or cold vinegar.

One cause of excessive menstruation, which sometimes recurs monthly, and continues for a fortnight at each period, and is succeeded by fluor albus during the intervals, I have suspected to arise, like the bleeding piles, from enlargement of the liver, which is liable to occur about the age of forty to those who have drank much strong small beer, or wine; or to those who have unfortunately been long accustomed to the use of tight stays, or other bandages round their bowels. In these situations 6 or 8 grains of rhubarb should be taken every night for months, or even years. Calomel, 4 or 6 grains should be taken as a cathartic one a month. A flannel dress on the legs, thighs, and lower body may be useful in the cold season, but injurious in the warmer months. Weak acid of vitriol ten drops, two or three times a day; steel in very small quantity; and a very loose dress round the body; are recommended.

12. Dysmenorrhagia. A difficulty of menstruation attended with pain. In this complaint the torpor of the uterine vessels, which precedes menstruation, is by sympathy accompanied with a torpor of the lumbar membranes, and consequent pain; and frequently with cold extremities, and general debility. The small quantity and difficulty of the discharge is owing to arterial inactivity, as in chlorosis. Whence it happens, that chalybeate medicines are of essicacy both to stop or prevent too great menstruation, and to promote or increase desicient menstruation; as the former is owing to inirritability of the veins, and the latter of the arteries of the uterus. See Article IV. 2. 6. in the Materia Medica.

M. M. Opium, steel, pediluvium. Warm bath.

13. Lochia nimia. Too great discharge after delivery. In that unnatural practice of some hasty accoucheurs of introducing the hand into the uterus immediately after the delivery of the child, and forcibly bringing away the placenta, it frequently happens, that a part of it is left behind; and the uterus, not having power to exclude so small a portion of it, is prevented from complete contraction, and a great hæmorrhage ensues. In this circumstance a bandage with a thick compress on the lower part of the belly, by appressing the sides of the uterus on the remaining part of the placenta, is likely to check the hæmorrhage, like the application of a pledget of any soft substance on a bleeding vessel.

In other cases the lochia continues too long, or in too great

quantity, owing to the deficiency of venous abforption.

M. M. An enema. An opiate. A blifter. Slight calybeates. Peruvian bark. Cloths dipped in cold vinegar and applied

externally. Bandages on the limbs to keep more blood in them for a time have been recommended.

liable to fpontanea. Some delicate ladies are perpetually liable to fpontaneous abortion, before the third, or after the feventh, month of gestation. From some of these patients I have learnt, that they have awakened with a slight degree of dissipult respiration, so as to induce them to rise hastily up in bed; and have hence suspected, that this was a tendency to a kind of asthma, owing to a desicient absorption of blood in the extremitics of the pulmonary or bronchial veins; and have concluded from thence, that there was generally a desiciency of venous absorption; and that this was the occasion of their frequent abortion. Which is further countenanced, where a great sanguinary dis-

charge precedes or follows the exclusion of the fetus.

Miscarriages are sometimes induced by what is termed a retroversion of the uterus, in which the fundus uteri is retroverted and pressed down between the rectum and the vagina. This can only occur in the first or second month of gestation, and is generally preceded by a dissiculty of making water, and a consequent tumour of the bladder; a violent pain about the perinceum or rectum is thus caused, and a miscarriage is liable to follow. Draw off the urine with a catheter; inject an enema with fixty drops of tincture of opium, if it can be done. If it recurs frequently after the miscarriage, a wax candle, or a pessary, made by rolling some emplastrum de minio spread on linen, may be introduced into the rectum, and worn as a compress to prevent the return for a few days, till the parts recover their strength. See London Medical Observations, Vol. IV. p. 388. and Dr. Hunter's Tables of the Gravid Uterus.

M. M. Opium, bark, chalybeates in small quantity. Change to a warmer climate. I have directed with success in sour cases half a grain of opium twice a day for a fortnight, and then a whole grain twice a day during the whole gestation. One of these patients took besides twenty grains of Peruvian bark for several weeks. By these means being exactly and regularly persisted in, a new habit became established, and the usual miscar-

riages were prevented.

Miscarriages more frequently happen from eruptive fevers, and from rheumatic ones, than from other inflammatory diseases. I saw a most violent pleurify and hepatitis cured by repeated vene-fection about a week or ten days before parturition; yet another lady whom I attended, miscarried at the end of the chicken pox, with which her children were at the same time affected. Miscarriages towards the termination of the small-pox are very frequent, yet there have been a few instances of children, who have been

born

born with the eruption on them. The blood in the small pox will not inoculate that disease, if taken before the commencement of the secondary sever; as shewn in Sect. XXXIII. 2. 10. because the contagious matter is not yet formed, but after it has been oxygenated through the cuticle in the pustules, it becomes contagious; and if it be then absorbed, as in the secondary sever, the blood of the mother may become contagious, and insect the child. The same mode of reasoning is applicable to the chicken pox. See Class IV. 3. 1. 7.

15. Scorbutus. Sea-scurvy is caused by falt diet, the perpetnal stimulus of which debilitates the venous and absorbent systems; and may also be promoted by the sea-air, which is known to be so injurious to most vegetables, which grow near the coasts, and has been perhaps incautiously recommended to consumptive patients. See Class II. 1.6.7. Hence the blood is imperfectly taken up by the veins from the capillaries, whence brown and black spots appear upon the skin without sever. The limbs become livid and edematous, and lastly ulcers are produced from descient absorption. See Sect. XXXIII. 3. 2. and Class II. 1. 4. 13. For an account of the scurvy of the lungs, see Sect. XXVII. 2.

M. M. Fresh animal and vegetable food. Infusion of malt. New beer. Sugar. Wine. Steel. Bark. Sorbentia. Opium?

to. Vibices. Extravafations of blood become black from their being fecluded from the air. The extravafation of blood in bruiles, or in some fevers, or after death in some patients, especially in the parts which were exposed to pressure, is owing to the fine terminations of the veins having been mechanically compressed so as to prevent their absorbing the blood from the capillaries, or to their inactivity from disease. The blood when extravasated undergoes a chemical change before it is sufficiently sluid to be taken up by the lymphatic absorbents, and in that

process changes its colour to green and then yellow.

17. Petechia. Purple spots. These attend severs with great venous inirritability, and are probably formed by the inability of a single termination of a vein, whence the corresponding capillary becomes ruptured, and effuses the blood into the cellular membrane round the inert termination of the vein. This is generally esteemed a sign of the putrid state of the blood, or that state contrary to the inslammatory one. As it attends some inflammatory diseases which are attended with great inirritability, as in the confluent small pox. But it also attends the scurvy, where no sever exists, and it therefore simply announces the inactivity of the terminations of some veins; and is thence indeed a bad symptom in severs, as a mark of approaching inactivity of

the whole fanguiferous system, or death. The blue colour of some children's arms or faces in very cold weather is owing in like manner to the torpor of the absorbent terminations of the the veins, whence the blood is accumulated in them, and sometimes bursts them. See Hæmorrhagia venosa, and Suppl. 1. 2. 7.

In some cases of sever attended with petechiæ, Dr. Hall, of Colchester, directed the body to be washed with cold vinegar and water twice a day, with great advantage. The petechiæ became daily less numerous and less livid, the pulse flower and stronger, with less delirium, and more sleep. He has treated twenty cases in this manner, and not lost one. Medical Review, Vol. III. p. 8.

In these cases not only the application of external cold seems to have been of service, by preventing the unnecessary expenditure of animal power; but as the stimulus of vinegar renders the lips pale, when applied externally, and in consequence stimulates the terminations of the veins into greater action; it seems

also to have contributed to remove the Petechiæ.

18. Aneurifma. Aneurifm is probably owing to the want of due irritability of a part of the coat of an artery. As living muscles are known to resist diruption more than dead ones, according to the experiments (I think) of Dr. Langrish, it follows that when a part of the coat of an artery ceases to contract by the stimulus of the blood, that it will soon become distended by the force of it, till it widens into a fack, and at last becomes ruptured.

M. M. Venefection repeatedly in small quantities. Rest. Diluent, mild nutriment. Daily evacuation by a pill confishing

of rhubarb eight grains, and foap four grains.

It is possible also, that an aneurism may be produced by the resistance to the circulation, and the force of the heart being

greater than the sides of the arteries can counterbalance.

Mr. Gimbernat is faid to have cured fome cases of an eurism in the popliteal artery by compressing it by means of an adapted machine, consisting of a steel ring above and below the knee, which are joined by a plate, beneath which is placed a proper cushion, which can be pressed on the distended part of the artery more or less by of means a screw. The other method of cure is by a double ligature above the aneurism, as first practised by Mr. J. Hunter.

19. Varix. The varix of veins occurs frequently in the legs of women, possibly sometimes from tight garters, and has for its proximate cause the inirritability of the coat of the vein; whence it becomes distended, till it burits, by the power with which the

blood

CLASS I. 2. 1. 19.

blood is thrown into it by the absorbent mouths, which take it

up from the capillary arteries.

M. M. Tie the vena faphena below the joint of the knee, and the blood will then circulate by the internal veins; and that ftopped in the veins beneath the ligature will be absorbed.

The piles may be termed varixes, and may be destroyed by

excision or ligature. See Hæmorrhois.

ORDO II.

Decreased Irritation.

GENUS II.

Decreased Action of the Secerning System.

THESE are always attended with decrease of partial, or of general heat; for as the heat of animal bodies is the consequence of their various secretions, and is perpetually passing away into the ambient air, or other bodies in contact with them; when these secretions become diminished, or cease, the heat of the part or of the whole is soon diminished, or ceases along with them.

SPECIES.

1. Frigus febrile. Febrile coldness. There is reason to believe, that the beginning of many fever-fits originates in the quiescence of some part of the absorbent system, especially where they have been owing to external cold; but that, where the coldness of the body is not owing to a diminution of external heat, it arises from the inaction of some part of the secerning system. Hence some parts of the body are hot whilst other parts are cold; which I suppose gave occasion to error in Martyn's Experiments; where he says, that the body is as hot in the cold paroxysms of severs as at other times.

After the fenforial power has been much diminished by great preceding activity of the system, as by long continued external heat, or violent exercise, a sudden exposure to much cold produces a torpor both greater in degree and over a greater portion of the system, by subtracting their accustomed stimulus from parts already much deprived of their irritability. Dr. Franklin in a letter to M. Duberge, the French translator of his works, mentions an instance of sour young men, who bathed in a cold spring after a day's harvest work; of whom two died on the spot, a third on the next morning, and the other survived with dissiculty. Hence it would appear, that those, who have to travel in intensely cold weather, will sooner perish, who have previously heated themselves much with drams, than those who have only the stimulus of natural food; of which I have heard one well attested instance. See Article VII. 2. 3. Class III.

Frigus chronicum. Permanent coldness. Coldness of the extremities.

tremities, without fever, with dry pale skin, is a symptom of general debility, owing to the decreased action of the arterial system, and of the capillary vessels; whence the perspirable matter is secreted in less quantity, and in consequence the skin is less warm. This coldness is observable at the extremities of the limbs, ears, and nose, more than in any other parts: as a larger surface is here exposed to the contact of the air, or clothes, and thence the heat is more hastily carried away.

The pain, which accompanies the coldness of the skin, is owing to the deficient exertion of the subcutaneous vessels, and probably to the accumulation of sensorial power in the extremities of their nerves. See Sect. XII. 5. 3. XIV. 6. XXXII. 3.

and Class I. 2. 4. 1.

M. M. A blister. Incitantia, nutrientia, forbentia. Exer-

cife. Clothes. Fire. Joy. Anger.

2. Pallor fugitivus. The fugitive paleness, which accompanies the coldness of the extremities, is owing to a less quantity of blood passing through the capillaries of the skin in a given time; where the absorbent power of the veins is at the same time much diminished, a part of the blood lingers at their junction with the capillary arteries, and a bluish tinge is mixed with the paleness; as is seen in the loose skin under the eye-lids, and is always a mark of temporary debility. See Class II. 1. 4. 4. Where the paleness of the skin is owing to the desciency of red globules in the blood, it is joined with a yellowish tinge; which is the colour of the serum, with which the blood then abounds, as in chlorosis, and in torpor or paralysis of the liver, and is often mistaken for a superabundance of bile.

A permanent paleness of the skin is owing to the coalescence of the minute arteries, as in old age. See Class I. 2. 2. 9. There is another source of paleness from the increased absorption of the terminations of the veins, as when vinegar is applied to the lips. See Sect. XXVII. 1. and another from the retrograde motions of the capillaries and fine extremities of the arteries.

See Class II. 3. 1. 1.

M. M. A blister, nutrientia, incitantia, exercise, oxygene gas.

3. Pus parcius. Diminished pus. Dryness of ulcers. In the cold fits of sever all the secretions are diminished, whether natural or artificial, as their quantity depends on the actions of the glands or capillaries, which then share in the universal inaction of the system. Hence the dryness of issues and blisters in great debility, and before the approach of death, is owing to deficient secretion, and not to increased absorption.

M. M. Opium, wine in very fmall quantities, Peruvian bark.

4. Mucus parcior. Diminished mucus. Dryness of the mouth

mouth and nostrils. This also occurs in the cold fits of intermittents. In these cases I have also found the tongue cold to the touch of the finger, and the breath to the back of one's hand, when opposed to it, which are very inautipicious symptoms, and generally fatal. In fevers with inirritability it is generally efteemed a good fymptom, when the nostrils and tongue become moist after having been previously dry; as it shews an increased action of the mucous glands of those membranes, which were before torpid. And the contrary to this is the facies Hippocratica, or countenance fo well described by Hippocrates, which is pale, cold, and thrunk; all which are owing to the inactivity of the fecerning vetlels, the palenels from there being lefs red blood paffing through the capillaries, the coldness of the skin from there being less secretion of perspirable matter, and the shrunk appearance from there being less mucus secreted into the cells of the cellular membrane. See Class IV. 2. 4. 11.

M. M. Blisters. Incitantia.

5. Urina parcier pallida. Paucity of pale urine, as in the cold fits of intermittents; it appears in some nervous fevers throughout the whole disease, and seems to proceed from a palfy of the kidneys; which probably was the cause of the sever, as the sever sometimes ceases, when that symptom is removed: hence the straw-coloured urine in this sever is so far salutary, as it shews the unimpaired action of the kidneys.

M. M. Balfams, effential oil, asparagus, rhubarb, a blister.

Cantharides internally.

6. Torpor hepaticus. Paucity of bile from a partial inaction of the liver; hence the bombycinous colour of the skin, grey stools, urine not yellow, indigestion, debility, followed by tym-

pany, dropfy, and death.

This paralysis or inirritability of the liver often destroys those who have been long habituated to much fermented liquor, and have suddenly omitted the use of it. It also destroys plumbers and house-painters, and in them seems a substitute for the colica saturnina. See Sect. XXX.

M. M. Aloe and calomel, then the bark, and chalybeates. Mercurial ointment rubbed on the region of the liver. Rhubarb, three or four grains, with opium half a grain to a grain twice a

day. Equitation, warm bath for half an hour every day.

7. Torpor pancreatis. Torpor of the pancreas. I saw what I conjectured to be a tumour of the pancreas with indigestion, and which terminated in the death of the patient. He had been for many years a great consumer of tobacco, insomuch that he chewed that noxious drug all the morning, and smoked it all the afternoon. As the secretion from the pancreas resembles taliva

Vol. II. in

in its general appearance, and probably in its office of affifting digestion, by preventing the fermentation of the aliment; as would appear by the experiments of Pringle and Macbride; there is reafon to suspect, that a sympathy may exist between the salivary and pancreatic glands; and that the perpetual stimulus of the former by tobacco might in process of time injure the latter. See Tobacco, Article III. 2. 2.

8. Torpor renis. Inirritability or paralysis of the kidneys is probably frequently mistaken for gravel in them. Several, who have lived rather intemperately in respect to fermented or spirituous liquors, become suddenly seized about the age of sixty, or later, with a total stoppage of urine; though they have previously had no symptoms of gravel. In these cases there is no water in the bladder; as is known by the introduction of the catheter, of which those made of elastic gum are said to be preferable to metallic ones; or it may generally be known by the shape of the abdomen, either by the eye or hand. Bougies and catheters of elastic gum are sold at No. 37, Red Lion-street, Holborn, London.

M. M. Electric shocks, warm bath. Emetics. See calculus renis, Class I. 1. 3. 9. When no gravel has been previously observed, and the patient has been a wine-drinker rather than an ale-drinker, the case is generally owing to inirritability of the tubuli uriniferi, and is frequently stall. See Class I. 2. 4. 20.

9. Puncte mucose vultus. Mucous spots on the face. These are owing to the inactivity of the excretory ducts of the mucous glands; the thinner part of this secretion exhales, and the remainder becomes inspissated, and lodges in the duct; the extremity of which becomes black by exposure to the air.

M. M. They may be pressed out by the singer-nails. Warm

water. Ether frequently applied. Blifter on the part?

blotches on the skin of the face and arms of elderly people, and frequently on their legs after slight erysipelas. The freckles on the face of younger people, who have red hair, seem to be a similar production, and seem all to be caused by the coalescence of the minute arteries or capillaries of the part. In a scar after a wound the integument is only opaque; but in these blotches, which are called morphew and freckles, the small vessels seem to have become inactive with some of the serum of the blood stagnating in them, from whence their colour. See Class III. 1. 2. 12.

M. M. Warm bathing. A blifter on the part?

animals for the purposes of anatomical preparations, the colour of the injected sluid will not pass into many very minute vessels; which

which nevertheless uncoloured water, or spirits, or quickfilver, will permeate. The same occurs in the filtration of some coloured study through paper, or very fine sand, where the colouring matter is not perfectly dissolved, but only dissussed through the liquid. This has led some to imagine, that the cause of the whiteness of the hair in elderly people may arise from the diminution, or greater tenuity, of the glandular vessels, which secrete the mucus, which hardens into hair; and that the same difference of the tenuity of the secenting vessels may possibly make the difference of colour of the silk from different silk-worms, which is of all shades from yellow to white.

But as the fecreted fluids are not the confequence of mechanical filtration, but of animal felection; we must look out for another cause, which must be found in the decreasing activity of the glands, as we advance in life; and which affects many of our other fecretions as well as that of the mucus, which forms the hair. Hence grey hairs are produced on the faces of horses by whatever injures the glands at their roots, as by corrosive blisters; and frequently on the human subject by external injuries on the head; and sometimes by severs. And as the grey colour of hair consists in its want of transparency, like water converted into snow; there is reason to suppose, that a defect of secreted moisture simply may be the cause of this kind of opacity, as explained in Cataracta, Class I. 2. 2. 13.

M. M. Whatever prevents the inirritability and infensibility of the system, that is, whatever prevents the approach of old age, will so far counteract the production of grey hairs, which is a symptom of it. For this purpose in people, who are not corpulent, and perhaps in those who are so, the warm bath twice or thrice a week is particularly serviceable. See Sect. XXXIX. 5.

1. on the colours of animals, and Class I. 1. 2. 15.

As mechanical injury from a percussion, or a wound, or a caustic, is liable to occasion the hair of the part to become grey; so I suspect the compression of parts against each other of some animals in the womb is liable to render the hair of those parts of a lighter colour; as seems often to occur in black cats and dogs. A small terrier bitch now stands by me, which is black on all those parts, which were external, when she was wrapped up in the uterus, teres atque rotunda; and those parts white, which were most constantly pressed together; and those parts tawny, which were generally but less constantly pressed together. Thus the hair of the back from the forehead to the end of the tail is black, as well as that of the sides, and external parts of the legs, both before and behind.

As in the uterus the chin of the whelp is bent down, and lies

in contact with the fore part of the neck and breast; the tail is applied close against the division of the thighs behind; the inside of the hinder thighs are pressed close to the sides of the belly, all

these parts have white hairs.

The fore-legs in the uterus lie on each fide of the face; fo that the feet cover part of the temples, and compress the prominent part of the upper eye-brows, but are so placed as to defend the eye-balls from pressure; it is curious to observe, that the hair of the sides of the face, and of the prominent upper eye-brows, are tawny, and of the inside of the feet and legs, which covered them; for as this posture admitted of more change in the latter weeks of gestation, the colour of these parts is not so far removed from black, as of those parts, where the contact or

compression was more uniform.

I have lately also inspected a male cat; who is quite black all over, except those parts which appear to have been solded together in the uterus; all which are perfectly white. In both these animals the parts compressed together are so distinctly defined by their colour, that the difference of the curvature and situation of them in the uterus may be nicely discerned: the hinder seet of the cat lay in the arm-pits of the fore-legs, and are white; her fore-legs crossed over the hinder thighs, and left on them a white mark; but the fore-seet, at least the hind part of them, lay under the tail; whence the fore-seet are tipped with white. Where the sectus is less tender, I suppose, this compression in the uterus does not affect it; as dogs and cats are perpetually seen, which are totally black.

Where this uterine compression of parts has not been so great as to render the hair white in other animals, it frequently happens, that the extremities of the body are white, as the feet, and nose, and tips of the ears of dogs and cats and horses, where the circulation is naturally weaker; whence it would seem, that the capillary glands, which form the hair, are impeded in the first instance by compression, and in the last by the debility of

the circulation in them. See Class I. 1. 2. 15.

This day, August 8th, 1794, I have seen a negro, who was born (as he reports) of black parents, both father and mother, at Kingston in Jamaica, who has many large white blotches on the skin of his limbs and body; which I thought felt not so foft to the singer, as the black parts. He has a white divergent blaze from the summit of his nose to the vertex of his head; the upper part of which, where it extends on the hairy scalp, has thick curled hair, like the other part of his head, but quite white. By these marks I supposed him to be the same black, who is described, when only two years old, in the Transactions of the Ameri-

can Philosophical Society, Vol II. page 292, where a female one is likewife described with nearly similar marks.

The joining of the frontal bones, and the bregma, having been later than that of the other futures of the cranium, probably gave cause to the whiteness of the hair on these parts by delaying or impeding its growth.

12. Callus. The callous skin on the hands and feet of laborious people is owing to the extreme vessels coalescing from the per-

petual preffure they are exposed to.

As we advance in life, the finer arteries lose their power of action, and their fides grow together; hence the paleness of the skins of elderly people, and the loss of that bloom, which is owing to the numerous fine arteries, and the transparency of the skin, that encloses them.

M. M. Warm bath. Paring the thick skin with a knife. Smoothing it with a pumice stone. Cover the part with oiled filk to prevent the evaporation of the perspirable matter, and

thus to keep it moist.

13. Cataracta is an opacity of the crystalline lens of the eye. It is a difease of light-coloured eves, as the gutta serena is of dark ones. On cutting off with fciffars the cornea of a calf's eye, and holding it in the palm of one's hand, fo as to gain a proper light, the artery, which fupplies nutriment to the crystalline humour, is eafily and beautifully feen; as it rifes from the centre of the optic nerve through the vitreous humour to the cryftalline. It is this point, where the artery enters the eye through the cineritious part of the optic nerve, (which is in part near the middle of the nerve,) which is without fensibility to light; as is shewn by fixing three papers, each of them about half an inch in diameter, against a wall about a foot distant from each other, about the height of the eye; and then looking at the middle one. withone eye, and retreating till you lose fight of one of the external papers. Now as the animal grows older, the artery becomes less visible, and perhaps carries only a transparent fluid, and at length in fome subjects I suppose ceases to be pervious; then it follows, that the crystalline lens, losing some sluid, and gaining none, becomes dry, and in confequence opaque; for the same reason, that wet or oiled paper is more transparent than when it is dry, as explained in Class I. 1.4. 1. The want of moisture in the cornea of old people. when the exhalation becomes greater than the supply, is the cause of its want of transparency; and which like the crystalline gains rather a milky opacity. The fame analogy may be used to explain the whiteness of the hair of old people, which loses its pellucidity along with its moisture. See Class I. 2. 2. 11.

M. M. Small electric shocks through the eye. A quarter of

a grain of corrolive fublimate of mercury diffolved in brandy, or taken in a pill, twice a day for fix weeks. Couching by depreffion, or by extraction. The former of these operations is much to be preferred to the latter, though the latter is at this time fo fashionable, that a surgeon is almost compelled to use it, lest he should not be thought an expert operator. For depressing the cataract is attended with no pain, no danger, no confinement, and may be as readily repeated, if the crystalline should rife again to the centre of the eye. The extraction of the cataract is attended with confiderable pain, with long confinement, generally with fever, always with inflammation, and frequently with irreparable injury to the iris, and confequent danger to the whole eye. Yet has this operation of extraction been trumpeted into universal fashion for no other reason but because it is difficult to perform, and therefore keeps the business in the hands of a few empirics, who receive larger rewards, regardless of the hazard, which is encountered by the flattered patient.

A friend of mine returned yesterday from London after an absence of many weeks; he had a cataract in a proper state for the operation, and in spite of my earnest exhortation to the contrary, was prevailed upon to have it extracted rather than depressed. He was confined to his bed three weeks after the operation, and is now returned with the iris adhering on one side so as to make an oblong aperture; and which is nearly, if not totally, without contraction, and thus greatly impedes the little vision, which he possesses. Whereas I saw some patients couched by depression many years ago by a then celebrated empiric, Chevalier Taylor, who were not confined above a day or two, that the eye might gradually be accustomed to light, and who saw as well as by extraction, perhaps better, without either pain, or inflam-

mation, or any hazard of lofing the eye.

As the inflammation of the iris is probably owing to forcing the crystalline through the aperture of it in the operation of extracting it, could it not be done more fafely by making the opening behind the iris and ciliary process into the vitreous humour? but the operation would still be more painful, more dangerous,

and not more useful than that by depressing it.

If extraction of the crystalline be used, Dr. Reimarus of Hamburgh advises to drop into the eye previous to the operation, some extract of belladonna dissolved in water, which he has sound to produce a temporary paralysis of the retina, and thence a total inaction of the iris, so that it remains persectly expanded, and is thence less liable to be injured by the operation, and the eye perhaps less liable to inflammation. Might not this be of advantage in some ophthalmies?

14. Innutritio

14. Innutritio offium. Innutrition of the bones. Not only the blood effused in vibices and petechiæ, or from bruises, as well as the blood and new vessels in inflamed parts, are reabsorbed by the increased action of the lymphatics; but the harder materials, which constitute the fangs of the first set of teeth, and the ends of exsoliating bones, and sometimes the matter of chalk-stones in the gout, the coagulable lymph, which is deposited on the lungs, or on the muscles after inflammation of those parts, and which frequently produces dissipationally the earthy part of the living bones are dissolved and absorbed by the increased actions of this

system of vessels. See Sect. XXXIII. 3. 1.

The earthy part of bones in this disease of the nutrition of them seems to suffer a solution, and reabsorption; while the secrning vessels do not supply a sufficient quantity of calcareous earth and phosphoric acid, which constitute the substance of bones. As calcarcous earth abounds every where, is the want of phosphoric acid the remote cause? One cause of this malady is given in the Philosophic Transactions, where the patient had been accustomed to drink large quantities of vinegar. Two cases are described by Mr. Gouch. In one case, which I saw, a considerable quantity of calcareous earth, and afterwards of bone-ashes, and of decoction of madder, and also of sublimate of mercury, were given without effect. All the bones became soft, many of them broke, and the patient seemed to die from the want of being able to distend her chest owing to the softness of the ribs.

M. M. Salt of urine, called fal microcofmicum, phosphorated foda. Calcined hartshorn. Bone-ashes. Hard or petrifying water, as that of Matlock, or such as is found in all limestone or marly countries. The calcareous earth in these waters might possibly be carried to the bones, as madder is known to colour them. Warm bath. Volatile or fixed alkali as a lotion on the

spine, or effential oils.

The innutrition of the bones is often first to be perceived by the difficulty of breathing and palpitation of the heart on walking a little faster than usual, which I suppose is owing to the soft-ness of the ends of the ribs adjoining to the sternum; on which account they do not perfectly distend the chest, when they are raised by the pectoral and intercostal muscles with greater force than usual. After this the spine becomes curved both by the softness of its vertebræ, and for the purpose of making room for the disturbed heart. See Species 16 of this Genus.

As these patients are pale and weak, there would seem to be deficiency of oxygene in their blood, and in consequence a desi-

ciency

ciency of phosphoric acid; which is probably produced by ox-

ygene in the act of respiration.

Mr. Bonhome, in the Chemical Annals, August, 1793, supposes the rickets to arise from the prevalence of vegetable or acetous acid, which is known to some bones out of the body. Mr. Dettaen seems to have espoused a similar opinion, and both of them in consequence give alkalies and testacea. If this theory was just, the soft bones of such patients should shew evident marks of such acidity after death; which I believe has not been observed. Nor is it analogous to other animal sacts, that nutritious sluids secreted by the sinest vessels of the body should be so little animalized, as to retain acetous or vegetable acidity.

The fuccess attending the following case in so short a time as a fortnight I ascribed principally to the use of the warm bath; in which the patient continued for full half an hour every night, in the degree of heat, which was most grateful to her sensation, which might be I suppose about 94. Miss ——, about ten years of age, and very tall and thin, has laboured under palpitation of her heart, and difficult breathing on the least exercise, with occasional violent dry cough, for a year or more, with dry lips, little appetite either for food or drink, and dry skin, with cold extremities. She has at times been occasionally worse, and been relieved in some degree by the bark. She began to bend forwards, and to lift up her shoulders. The former seemed owing to a beginning curvature of the spine, the latter was probably caused to facilitate her difficult respiration.

M. M. She used the warm bath, as above related; which by its warmth might increase the irritability of the smallest series of vessels, and by supplying more moisture to the blood might probably tend to carry further the materials, which form calcareous or bony particles, or to convey them in more dilute solution. She took twice a day twenty grains of extract of bark, twenty grains of foda phosphorata, and ten grains of chalk, and ten of calcined hartshorn mixed into a powder with ten drops of laudanum; with sless food both to dinner and supper; and port wine and water instead of the small beer she had been accustomed to; she lay on a sofa frequently in a day, and occasion-

ally used a neck-fwing.

There is no fituation, where the foftness of the bones and consequent deformity of them is so frequently attended with calamitous consequences, as when it affects the bones of the pelvis, so as to contract the form of it; whence many unfortunate women have lost their infants, or perished themselves. In this miserable situation of the pregnant uterus, some have destroyed the child, others have undergone the Cesarean operation,

and have thence generally perished themselves. But Dr. Denman has ingeniously introduced a new practice, which has faved. in fuch cases, both the mother and child; which is by promoting a premature delivery between the feventh and eighth months, before the child has acquired its full growth, which has been attended with fuccess. See Denman's Midwifery, and Medical Journal, Vol. III. No. 11.

In one instance, nature seems to have had a similar expedient, and perhaps to overcome a fimilar difficulty, in the premature birth of the progeny of the kanguroo; whose young are excluded from the uterus in a very early state of their growth, and received into an exterior bag; which is furnished with teats, to which they long adhere by their mouths, till they are ready for

a fecond birth.

15. Rachitis. Rickets. The head is large, protuberant chiefly on the forepart. The smaller joints are swelled; the ribs depressed; the belly tumid, with other parts emaciated. This diseafe from the innutrition or foftness of the bones arose about two centuries ago; feems to have been half a century in an increafing or spreading state; continued about half a century at its height, or greatest diffusion; and is now nearly vanished: which gives reason to hope, that the small-pox, measles, and venereal difease, which are all of modern production, and have already become milder, may in process of time vanish from the earth. and perhaps be succeeded by new ones! See the preceding

Species.

16. Spine distortio. Distortion of the spine is another disease originating from the innutrition or foftness of the bones. I once faw a child about fix years old with palpitation of heart, and quickness of respiration, which began to have a curvature of the fpine; I then doubted, whether the palpitation and quick respiration were the cause or consequence of the curvature of the fpine; fuspecting either that nature had bent the spine outwards to give room to the enlarged heart; or that the malformation of the cheft had compressed and impeded the movements of the heart. But a few weeks ago on attending a young lady about ten years old, whose spine had lately begun to be distorted, with very great difficulty and quickness of respiration, and alarming palpitation of the heart, I convinced myself, that the palpitation and difficult respiration were the effect of the change of the cavity of the chest from the distortion of the spine; and that the whole was therefore a disease of the innutrition or softness of the bones.

For on directing her to lie down much in the day, and to take the bark, the diffortion became lefs, and the palpitation and VOL. II. quick quick respiration became less at the same time. After this obfervation a neck-swing was directed, and she took the bark, madder, and bone-ashes; and she continues to amend both in

her shape and health.

Delicate young ladies are very liable to become awry at many boarding-schools. This is occasioned principally by their being obliged too long to preserve an erect attitude, by sitting on forms many hours together. To prevent this, the school-seats should have either backs, on which they may occasionally rest themselves; or desks before them, on which they may occasionally lean. This is a thing of greater consequence than may appear to those, who have not attended to it.

When the least tendency to become awry is observed, they should be advised to lie down on a bed or fofa for an hour in the middle of the day for many months; which generally prevents the increase of this deformity by taking off for a time the pressure on the spine of the back, and it at the same time tends to make them grow taller. Young persons, when nicely measured, are found to be half an inch higher in a morning than at night; as is well known to those who inlist very young men for foldiers. This is owing to the cartilages between the bones of the back becoming compressed by the weight of the head and shoulders on them during the day. It is the same pressure which produces curvatures and diffortions of the spine in growing children, where the bones are fofter than usual; and which may thus be relieved by an horizontal posture for an hour in the middle of the day, or by being frequently allowed to lean on a chair, or to play on the ground on a carpet.

Young ladies should also be directed, where two sleep in a bed, to change every night, or every week, their sides of the bed; which will prevent their tendency to sleep always on the same side; which is not only liable to produce crookedness, but also to occasion diseases by the internal parts being so long kept in uniform contact as to grow together. For the same reason they should not be allowed to sit always on the same side of the sire or window, because they will then be inclined too frequently to

bend themselves to one side.

Another great cause of injury to the shape of young ladies is from the pressure of stays, or other tight bandages, which at the same time cause other diseases by changing the form or situation of the internal parts. If a hard part of the stays, even a knot of the thread, with which they are sewed together, is pressed hard upon one side more than the other, the child bends from the side most painful, and thus occasions a curvature of the spine. To counteract this effect, such stays as have sewest hard parts,

and especially such as can be daily or weekly turned, are preferable to others.

Where frequent lying down on a fofa in the day-time, and fwinging frequently for a short time by the hands or head, with loofe drefs, do not relieve a beginning distortion of the back; recourse may be had to a chair with stuffed moveable arms for the purpose of suspending the weight of the body by cushions under the arm-pits, like resting on crutches, or like the leading-strings of infants. From the top of the back of the fame chair a curved fteel bar may also project to suspend the body occasionally, or in part by the head, like the fwing above mentioned. The . use of this chair is more efficacious in straightening the spine, than fimply lying down horizontally; as it not only takes off the pressure of the head and shoulders from the spine, but at the fame time the inferior parts of the body contribute to draw the fpine straight by their weight; or lastly, recourse may be had to a spinal machine first described in the Mémoires of the academy of furgery in Paris, Vol. III. p. 600, by M. Le Vacher, and fince made by Mr. Jones, at No. 6, North-street, Tottenham court-road, London, which suspends the head, and places the weight of it on the hips. This machine is capable of improvement by joints in the bar at the back of it, to permit the body to bend forwards without diminishing the extension of the spine.

The objections of this machine of M. Vacher, which is made by Mr. Jones, are first, that it is worn in the day-time, and has a very unsightly appearance. Mr. Jones has endeavoured to remedy this, by taking away the curved bar over the head, and substituting in its place a forked bar, rising up behind each ear, with webs fastened to it, which pass under the chin and occiput. But this is not an improvement, but a deterioration of M. Vacher's machine, as it prevents the head from turning with facility to either side. Another objection is, that its being worn, when the muscles of the back are in action, it is rather calculated to prevent the curvature of the spine from becoming greater, than to extend

the spine, and diminish its curvature.

For this latter purpose I have made a steel bow, which receives the head longitudinally from the forehead to the occiput; having a fork furnished with a web to sustain the chin, and another to sustain the occiput. The summit of the bow is sixed by a swivel to the board going behind the head of the bed above the pillow. The bed is to be inclined from the head to the feet about twelve or sixteen inches. Hence the patient would be constantly sliding down during sleep, unless supported by this bow, with webbed forks, covered also with fur, placed beneath the chin, and beneath the occiput. There are also proper webs

lined with fur for the hands to take hold of occasionally, and alfo to go under the arms. By these means I should hope great
advantage from gradually extending the spine during the inactivity of the muscles of the back; and that it may be done without disturbing the sleep-of the patient, and if this should happen, the bow is made to open by a joint at the summit of it, so as
to be instantly disengaged from the neck by the hand of the
wearer. This bow I have now used with advantage on one patient, and it may be had from Mr. Harrison, whitesmith, Bridgegate, Derby.

It is also possible that a slight compress on the prominent part of a curved spine might be applied with advantage both in sleep and in waking hours, if it could be nicely held on the part by a weak and very flexible fpring, with a proper counter-pressure on fome distant part; but this would require more art than could be managed, except by those who have very accurate mechanical ideas, and must differ with every kind of curvature. Thus if the prominent part of the curve of the spine be on one side, a stuffed cushion fixed to the centre of a long thin steel spring should be applied on the prominence; one end of this long fpring should be bent by a strap joined to a waistcoat on the opposite shoulder, and the other end of it by a strap joined to drawers on the opposite hip; the degree of pressure to be adjusted by the tightness of these straps. If the prominent part of a curved spine be exactly behind, the ends of the long spring should extend from the lowest bone of the neck to the os coccigis, and should have its two ends attached to the top of a waistcoat, and to the wailthand of a pair of drawers.

It will be from hence easily perceived, that all other methods of confining or directing the growth of young people should be used with great skill; such as back boards, or bandages, or stocks for the feet; and that their application should not be continued too long at a time, lest worse consequences should ensue, than the deformiry they were designed to remove. To this may be added, that the stiff erect attitude taught by some modern dancing masters does not contribute to the grace of person, but rather militates against it; as is well seen in one of the prints in Hogarth's Analysis of Beauty; and is exemplished by the easy grace of some of the ancient statues, as of the Venus de Medicis, and the Antinous, and in the works of some modern artists, as in a beautiful print of Hebe feeding an Eagle, painted by Hamilton, and engraved by Eginton, and many of the figures of Angelica Kaussman.

Where the bone of one of the vertebræ of the back has been welled on both fides of it, fo as to become protuberant, iffues

near the swelled part have been found of great service, as mentioned in Species 18 of this Genus. This has induced me to propose in curvatures of the spine, to put an issue on the outside of the curve, where it could be certainly ascertained, as the bones on the convex side of the curve must be enlarged; in one case I thought this of service, and recommend the further trial of it.

In the tendency to curvature of the spine, whatever strengthens the general constitution is of service; as the use of the cold bath in the fummer months. This however requires fome re-Ariction both in respect to the degree of coldness of the bath, the time of continuing in it, and the feason of the year. Common fprings, which are of forty-eight degrees of heat, are too cold for tender constitutions, whether of children or adults, and frequently do them great and irreparable injury. The coldness of river-water in the fummer months, which is about fixty-eight degrees, or that of Matlock, which is about fixty-eight, or of Buxton, which is eighty-two, are much to be preferred. The time of continuing in the bath should be but a minute or two, or not fo long as to occasion a trembling of the limbs from cold. In respect to the season of the year, delicate children should certainly only bathe in the fummer months; as the going frequently into the cold air in winter will answer all the purposes of the cold bath.

17. Claudicatio conaria. Lameness of the hip. A nodding of the thigh-bone is faid to be produced in feeble children by the foftness of the neck or upper part of that bone beneath the cartilage; which is naturally bent, and in this difease bends more downwards, or nods, by the pressure of the body; and thus renders one leg apparently shorter than the other. In other cases the end of the bone is protruded out of its socket, by inflammation or enlargement of the cartilages or ligaments of the joint, so that it rests on some part of the edge of the acetabulum, which in time becomes filled up. When the legs are straight, as in standing erect, there is no verticillary motion in the knee-joint; all the motion then in turning out the toes further than nature defigned, must be obtained by straining in some degree this head of the thigh-bone, or the acetabulum, or cavity, in which it moves. This has induced me to believe, that this misfortune of the nodding of the head of the bone, or partial diflocation of it, by which one leg becomes shorter than the other, is fometimes occasioned by making very young children stand in what are called stocks; that is with their heels together, and their toes quite out. Whence the focket of the thigh-bone becomes inflamed and painful, or the neck of the bone is bent downward and outwards.

In this case there is no expectation of recovering the straightness of the end of the bone; but these patients are liable to another missortune, that is, to acquire afterwards a distortion of the spine; for as one leg is shorter than the other, they sink on that side, and in consequence bend the upper part of their bodies, as their shoulders, the contrary way, to balance themselves; and then again the neck is bent back again towards the lame side, to preserve the head perpendicular; and thus the sigure becomes quite distorted like the letter S, owing originally to the desiciency of the length of one limb. The only way to prevent this curvature of the spine is for the child to wear a high-healed shoe or patten on the lame soot, so as to support that side on the same level with the other, and thus to prevent a greater deformity.

I have this day feen a young lady about twelve, who does not limp or waddle in walking; but neverthelefs, when the stands or fits, she finks down towards her right side, and turns out that toe more than the other. Hence, both as she sits and stands, she bends her body to the right; whence her head would hang a little over her right shoulder; but to replace this perpendicularly, she lifts up her left shoulder and contracts the muscles on that side of the neck; which are therefore become thicker and stronger by their continued action; but there is not yet any very

perceptible distortion of the spine.

As her right toe is turned outward rather more than natural, this shews the disease to be in the hip-joint; because, when the limb is stretched out, the toe cannot turn horizontally in the least without moving the end of the thigh-bone; although when the knee is bent, the toe can be turned through one third or half of a circle by the rotation of the tibia and fibula of the leg round each other. Hence if children are set in stocks with their heels touching each other as they sit, and are then made to rise up, till they stand erect, the socket or head of the thigh-bone becomes injured, especially in those children, whose bones are soft; and a shortness of that limb succeeds either by the bending of the neck of the thigh-bone, or by its getting out of the acetabulum; and a consequent rising of one shoulder, and a curvature of the spine are produced from so distant a cause.

M. M. An elaftic cushion made of curled hair should be placed under the affected hip, whenever she sits; or should be fitted to the part by means of drawers, so that she cannot avoid sitting on it. A neck-swing, and lying down in the day, should be occasionally used to prevent or remove any curvature of the

spine. The rest as in Species 13 and 15 of this genus.

18. Spina protuberans. Protuberant spine. One of the bones

of the spine swells, and rises above the rest. This is not an uncommon discase, and belongs to the innutrition of the bones, as the bone must become soft before it swells; which softness is owing to defect of the secretion of phosphorated calcareous earth. The swelling of the bone compresses a part of the brain, called the spinal marrow, within the cavity of the back-bones; and in consequence the lower limbs become paralytic, attended sometimes with difficulty of emptying the bladder and rectum.

M. M. Issues put on each side of the prominent bone are of great effect, I suppose, by their stimulus; which excites into action more of the sensorial powers of irritation and sensation, and thus gives greater activity to the vascular system in their vicinity. The methods recommended in distortion of the spine

are also to be attended to.

19. Spina bifida. Divided fpine, called also Hydrorachitis, as well as the Hydrocephalus externus, is probably owing in part to a defect of offification of the spine and cranium; and the collection of sluid beneath them may originate from the general debility of the system; which affects both the secerning, and abforbent vessels.

A curious circumstance, which is affirmed to attend the spina bissida, is, that on compressing the tumor with the hand gently, the whole brain becomes affected, and the patient falls assept. I suppose the same must happen on compressing the hydrocephalus

externus? See Sect. XVIII. 20.

20. Offis palati defectus. A defect of the bone of the palate, which frequently accompanies a division of the upper lip, occurs before nativity; and is owing to the deficient action of the fecerning system, from whence the extremities are not completed. From a similar cause I have seen the point of the tongue descient, and one joint of the two least singers, and of the two least toes, in the same infant; who was otherwise a sine girl. See Sect. XXXIX. 4.4.

The operation for the hare lip is described by many surgical writers; but there is a person in London, who makes very ingenious artificial palates; which prevent that desect of speech, which attends this malformation. This sactitious palate consists of a thin plate of silver of the shape and form of the roof of the mouth; from the front edge to the back edge of this silver plate four or sive holes are made in a straight line large enough for a needle to pass through them; on the back of it is then sewed a piece of sponge; which when expanded with moisture is nearly as large as the silver plate. This sponge is slipped through the division of the bone of the palate, so as to lie above it, while the silver

plate

plate covers the aperture beneath, and is suspended by the expanding sponge. This is removed every night and washed, and returned into its place in the morning; on this account it is convenient to have five or fix of them, for the sake of cleanlines. I have been more particular in describing this invention, as I do not know the name, or place of residence, of the maker.

ORDO II.

Decreased Irritation.

GENUS III.

With decreased Action of the Absorbent System.

Some decrease of heat attends these diseases, though in a less degree than those of the last genus, because the absorbent system of glands do not generate so much heat in their healthy state of action as the secerning system of glands, as explained in Class 1. 1. 3.

SPECIES.

1. Mucus faucium frigidus. Cold mucus from the throat. Much mucus, of rather a faline tafte, and lefs inspiffated than utual, is evacuated from the fauces by hawking, owing to the deficient abtorption of the thinner parts of it. This becomes a habit in some elderly people, who are continually spitting it out of their mouths; and has probably been brought on by taking snuff, or smoking tobacco; which by frequently stimulating the fauces have at length rendered the absorbent vessels less excitable by the natural stimulus of the saline part of the secretion, which ought to be reabsorbed, as soon as secreted.

M. M. A few grains of powder of bark frequently put into the mouth, and gradually diffused over the fauces. A gargle of

barley water.

2. Sudor frigidus. The cold dampness of the hands of some people is caused by the deficient absorption of perspirable matter; the clammy or viscid feel of it is owing to the mucous part being left upon the skin. The coldness is produced both by the decreased action of the absorbent system, and by the evaporation of a greater quantity of the perspirable matter into the air, which ought to have been absorbed.

M. M. Wash the hands in lime water, or with a small quan-

tity of volatile alkali in water.

3. Catarrhus frigidus. The thin discharge from the nostrils in cold weather. The absorbent vessels become torpid by the diminution of external heat, sooner than the secenting ones, which are longer kept warm by the circulating blood, from which they select the sluid they secrete; whereas the absorbent Vol. II.

vessels of the nostrils drink up their fluids, namely the thin and faline part of the mucus, after it has been cooled by the atmosphere. Hence the absorbents ceasing to act, and the secerning vessels continuing some time longer to pour out the mucus, a copious thin discharge is produced, which trickles down the nostrils in cold weather. This discharge is so acrid as to inflame the upper lip; which is owing to the neutral salts, with which it abounds, not being reabsorbed; so the tears in the fistula lach-

rymalis inflame the cheek. See Class I. 1. 2. 7.

4. Expectoratio frigida. Cold expectoration. Where the pulmonary abforption is deficient, an habitual cough is produced. and a frequent expectoration of thin faline mucus; as is often feen in old enfeebled people. Though the stimulus of the faline fluid, which attends all fecretions, is not sufficient to excite the languid absorbent vessels to imbibe it; yet this faline part, together with the increased quantity of the whole of the secreted mucus, stimulates the branches of the bronchia, so as to induce an almost incessant cough to discharge it from the lungs. A fingle grain of opium, or any other stimulant drug, as a wine posset with spirit of hartshorn, will cure this cold cough, and the cold catarrh of the preceding article, like a charm, by ftimulating the torpid mouths of the absorbents into action. Which has given rife to an indifcriminate and frequently pernicious use of the warm regimen in coughs and catarrhs of the warm or inflammatory kind, to the great injury of many.

M. M. Half a grain of opium night and morning promotes the absorption of the more fluid and faline parts, and in confequence thickens the mucus, and abates its acrimony. Warm

diluent drink, wine-whey, with volatile alkali.

5. Uring uberior pallida. On being exposed naked to coldair, or sprinkled with cold water, a quantity of pale urine is soon discharged; for the absorbents of the bladder become torpid by their sympathy with those of the skin; which are rendered quiescent by the diminution of external heat; but the kidneys continue to secrete the urine, and as no part of it is absorbed, it becomes copious and pale. This happens from a similar cause in cold fits of agues; and in less degree to many debilitated constitutions, whose extremities are generally cold and pale. The great quantity of limpid water in hysteric cases, and in diabetes, belongs to Class I. 3. 1. 10. I. 3. 2. 6.

M. M. Tincture of cantharides, opium, alum, forbentia. Flannel shirt in cold weather. Animal food. Beer. Wine.

Friction. Exercise. Fire.

6. Diarrhæa frigida. Liquid stools are produced by exposing

the body naked to cold air, or fprinkling it with cold water, for the fame reason as the last article.

But this disease is sometimes of a dangerous nature; the intestinal absorption being so impaired, that the aliment is said to come away undiminished in quantity, and almost unchanged by

the powers of digestion, and is then called lientery.

The mucus of the rectum fometimes comes away like pellucid hartshorn jelly, and liquefies by heat like that, towards the end of inirritative fevers, which is owing to the thinner part of the mucus not being absorbed, and thus resembles the catarrh of some old people.

M. M. Opium, campechy wood, armenian bole. Blifter. Flannel thirt in cold weather. Clysters with opium. Friction on the bowels morning and night. Equitation twice a day.

7. Fluor albus frigidus. Cold fluor albus. In weak conflitutions, where this discharge is pellucid and thin, it must proceed from want of absorption of the mucous membrane of the vagina, or uterus, and not from an increased secretion. This I suspect to be the most frequent kind of fluor albus; the former one described at Class I. 1. 2. 11. attends menstruation, or is a discharge instead of it, and thus resembles the venereal orgasm of female quadrupeds. The discharge in the cold kind being more faline, is liable to excoriate the part, and thus produce smarting in making water; in its great degree it is difficult to cure.

M. M. Increase the evacuation by stool and by perspiration, by taking rhubarb every night, about fix or ten grains with one grain of opium for some months. Flannel shirt in winter. Balsam copaiva. Gum kino, bitters, chalybeates, friction over the whole Tkin with flannel morning and night. Partial cold bath, by sprinkling the loins and thighs, or sponging them with cold water. Mucilage as ifinglass boiled in milk; blanc mange, hartshorn jelly, are recommended by some. Tincture of cantharides sometimes seems of service given from ten to twenty drops or more, three or four times a day. A large plaster of burgundy pitch and armenian bole, so as to cover the loins and lower part of the belly, is faid to have fometimes succeeded by increasing absorption by its compression in the manner of a bandage. A folution of metallic falts, as white vitriol, fixty grains to a pint; or an infusion of oak-bark may be injected into the vagina. Cold bath.

8. Gonorrhæa frigida. Cold gleet. Where the gleet is thin and pellucid, it must arise from the want of absorption of the membranes of the urethra, rather than from an increased secretion from them. This I suppose to be a more common disease

than that mentioned at Class I. I. 2. 10.

M. M. Metallic

M. M. Metallic injections, partial cold bath, internal method as in the fluor albus above described. Balsam of copaiva. Tincture of cantharides. Introduce a few inches into the urethra a bougie smeared with balfam of copaiva. See Home on urethra,

p. 105. o. Hepatis tumor. The liver becomes enlarged from defect of the absorption of mucus from its cells, as in anafarca, especially in feeble children; at the same time less bile is secreted from the torpid circulation in the vena portæ. And as the abforbents, which refume the thinner parts of the bile from the gall-bladder and hepatic ducts, are also torpid or quiescent, the bile is more dilute, as well as in less quantity. From the obstruction of the passage of the blood through the compressed vena porta these patients have tumid bellies, and pale bloated countenances; their paleness is probably owing to the deficiency of the quantity of red globules in the blood in confequence of the inert state of the bile.

These symptoms in children are generally attended with worms, the dilute bile and the weak digestion not destroying them. In Theep I have feen fluke-worms in the gall-ducts themselves among the dilute bile; which gall-ducts they eat through, and then produce ulcers, and the hectic fever, called the rot. See Class

I. 1. 4. 10. and Article IV. 2. 6.

M. M. After a calomel purge, crude iron filings are specific in this difease in children, and the worms are destroyed by the returning acrimony and quantity of the bile. A blifter on the region of the liver. Sorbentia, as worm-feed, fantonicum. Columbo. Bark.

The nitrous acid has been strongly recommended by Mr. Scot in tumours of the liver, which frequently occur in the east, where this gentleman resides; he gives two drachms of strong nitrous acid mixed with two pounds of water, to be drunk daily at in-

tervals. See Syphilis, Class II. 1. 5. 2.

10. Chlorofis. When the defect of the due action of both the absorbent and secerning vessels of the liver affects women, and is attended with obstruction of the catamenia, it is called chlorosis; and is cured by the exhibition of steel, which restores by its specific stimulus the absorbent power of the liver; and the menstruction, which was obstructed in consequence of debility,

Indigestion, owing to torpor of the stomach, and a consequent too great acidity of its contents, attend this difease; whence a defire of eating chalk, or marl. Sometimes a great quantity of pale urine is discharged in a morning, which is owing to the inaction of the absorbents, which are distributed on the neck of the bladder, during fleep. The fwelling of the ankles, which frequently attends chlorofis, is another effect of deficient action of the abforbent fystem; and the pale countenance is occasioned by the deficient quantity of red globules of blood, caused by the deficient quantity or acrimony of the bile, and consequent weakness of the circulation. The pulse is so quick in some cases of chlorofis, that, when attended with an accidental cough, it may be mistaken for pulmonary consumption. This quick pulse is owing to the debility of the heart from the want of stimulus occasioned by the deficiency of the quantity, and acrimony of the blood.

M. M. Steel. Bitters. Conftant moderate exercife. Friction with flannel all over the body and limbs night and morning. Rhubarb five grains, opium half a grain, every night. Flesh diet, with small beer, or wine and water. The disease continues some months, but at length subsides by the treatment above described. A bath of about eighty degrees, as Buxton

Bath, is of fervice; a colder bath may do great injury.

11. Hydrocele. Dropfy of the vagina testis. Dropsies have been divided into the encyfted and the diffused, meaning those of the cellular membrane, the cells of which communicate with each other like a sponge, and those of any other cavity of the body. The collections of mucous fluids in the various cells and cavities of the body arise from the torpor of the absorbent vessels of those parts. It is probable, that in dropfies attended with great thirst the cutaneous abforbents become paralytic first; and then from the great thirst, which is thus occasioned by the want of atmospheric moisture, the absorption of the fat ensues; as in fevers attended with great thirst, the fat is quickly taken up. See Obefitas I. 2. 3. 16. Some have believed, that the cellular and adipose membranes are different ones; as no fat is ever deposited in the eyelids or fcrotum, both which places are very liable to be distended with the mucilaginous fluid of the anasarca, and with air in Emphysema. Sometimes a gradual absorption of the accumulated fluid takes place, and the thinner parts being taken up, there remains a more viscid fluid, or almost a solid in the part, as in some swelled legs, which cannot easily be indented by the preffure of the finger, and are called fcorbutic. Sometimes the paralysis of the absorbents is completely removed, and the whole is again taken up into the circulation.

The Hydrocele is known by a tumor of the scrotum, which is without pain, gradually produced, with fluctuation, and a degree of pellucidity, when a candle is held behind it; it is the most simple incysted dropfy, as it is not in general complicated with other diseases, as ascites with scirrhous liver, and hydro-

cephalus

cephalus internus, with general debility. The cure of this difease is effected by different ways; it consists in discharging the water by an external aperture; and by so far inflaming the cyst and testicle, that they afterwards grow together, and thus prevent in future any secretion or effusion of mucus; the disease is thus cured, not by the revivescence of the absorbent power of the lymphatics, but by the prevention of secretion by the adhesion of the vagina to the testis. This I believe is performed with less pain, and is more certainly manageable by tapping, or discharging the sluid by means of a trocar, and after the evacuation of it to fill the cyst with a mixture of wine and water for a few minutes till the necessary degree of stimulus is produced, and then to withdraw it; as recommended by Mr. Earle. See also Medical Commentaries by Dr. Duncan for 1793.

12. Hydrocephalus internus, or dropfy of the ventricles of the brain, is fatal to many children, and fome adults. When this disease is less in quantity, it probably produces a fever, termed a nervous sever, and which is sometimes called a worm sever, according to the opinion of Dr. Gilchrist, in the Scots Medical Essays. This sever is attended with great inirritability, as appears from the dilated pupils of the eyes, in which it corresponds with the dropfy of the brain. And the latter disease has its paroxysms of quick impulse, and in that respect corresponds with other

er fevers with inirritability.

The hydrocephalus internus is diffinguished from apoplexy by its being attended with fever, and from nervous fever by the paroxysms being very irregular, with perfect intermissions many times in a day. In nervous fever the pain of the head generally affects the middle of the forehead; in hydrocephalus internus it is generally on one side of the head. One of the earliest criterions is the patient being uneasy on raising his head from the pillow, and wishing to lie down again immediately; which I suppose is owing to the pressure of the water on the larger trunks of the blood-vessels entering the cavity being more intolerable than on the smaller ones; for if the larger trunks are compressed, it must inconvenience the branches also; but if some of the small branches are compressed only, the trunks are not so immediately incommoded.

Blifters on the head, and mercurial ointment externally, with calomel internally, are principally recommended in this fatal difease. When the patient cannot bear to be raised up in bed without great uneasiness, it is a bad symptom. So I believe is deafness, which is commonly mistaken for stupor. See Class I. 2. 5. 6. And when the dilatation of the pupil of either eye, or the squinting is very apparent, or the pupils of both eyes much dilatation.

ted, it is generally fatal. As by stimulating one branch of lymphatics into inverted motion, another branch is liable to abforb its fluid more haftily; fuppose strong errhines, as common tobacco fnuff to children, or one grain of turpeth mineral, (hydrargyrus vitriolatus), mixed with ten or fifteen grains of fugar, were gradually blown up the nostrils? See Class I. 3. 2. 1. I have tried common fnuff upon two children in this disease; one could not be made to fneeze, and the other was too near death to receive advantage. When the mercurial preparations have produced falivation, I believe they may have been of fervice, but I doubt their good effect otherwise. In one child I tried the tincture of digitalis; but it was given with too timid a hand, and too late in the difease, to determine its effects. See Sect. XXIX. 5. 9.

As all the above remedies generally fail of fuccess, I think frequent, almost hourly, shocks of electricity from very small charges might be passed through the head in all directions with probability of good event; as by Volta's rods of zinc and filver described in Class I. 2. 5. 5. A solution of hydrargyrus muriatus, corrolive sublimate of mercury in rectified spirit of wine, three grains to an ounce, is faid to produce instantaneous and violent falivation; as described in Class II. 1. 5. 1. on Gonorrheea. Could a small quantity of this violent stimulus be used according to the age of the child with probable good effect? Could the trephine be used with safety or advantage where the affected fide can be diftinguished? See Strabismus, Class I. 2. 5. 4. When one eye is affected, does the disease exift in the ventricle of that side?

The following extract from a letter of Dr. Beddoes on hydro-

cephalus internus, is well worthy to be attended to.

"Master L-, aged 9 years, became suddenly ill in the night about a week before I faw him. On the day before the attack, he had taken opening medicines, and had bathed afterwards. He had complained of violently acute pain in his head, shrieked frequently, ground his teeth hard, could not bear to have his head raised from the pillow, and was torpid or deaf. His tongue was white, pulse 110 in the evening and full. As yet the pupil of the eye was irritable, and he had no strabifmus. He had been bled with leeches about the head, and bliftered. Idirected mercurial inunction, and calomel from 3 to 6 grains to be taken at first every six, and afterwards every three hours. This plan produced no sensible effect, and the patient died on the 18th day after the feizure. He had convultion-fits two days preceding his death, and the well-known fymptoms of hydrocephalus internus all made their appearance. From what I had feen

feen and read of this disease, I believed it to belong to inflammations, and at an earlier period I should be tempted to bleed as largely as for pneumonia. The fluid found after death in the ventricles of the brain I impute to debility of the absorbents induced by inflammation. My reasons are briefly these: 1. The acuteness of the pain. 2. The state of the pulse. In the above cafe for the first o or 10 days it did not exceed 110, and was full and strong. 3. To find out whether any febrile alternations took place, Master L.'s feet were frequently felt, and they were found at times cold, and at other times of a dry heat. I have many times feen this difeafe, but the patients were too young, or too far advanced, to inform me, whether they had chillness succeeded by heat at its onfet. 4. The diforders to which the young are more peculiarly liable afford a prefumption, that hydrocephalus internus is an inflammatory difease; and this is confirmed by the regularity of the period, within which it finishes its course. And lastly, does not happen more frequently than is suspected from external injury?

"I have just now been well informed, that Dr. Rush has lately cured five out of fix patients by copious bleedings. I relate here the reasons for an opinion without pretending to a discovery. Something like this doctrine may be found in certain modern publications, but it is delivered in that vague and diffuse style, which I trust your example will band from medi-

cal literature."

To this idea of Dr. Beddoes may be added, that the hydrocele generally fucceeds an injury, and confequent inflammation of the bag, which contains it. And that other dropfies, which principally attend inebriates, are confequent to too great action of the mucous membranes by the stimulus of beer, wine, and spirits. And lastly, that as these cases of hydrocephalus end so fatally, a new mode of treating them is much to be desired, and deserves to be seriously attended to.

This idea of inflammation preceding hydrocephalus was mentioned by Dr. Q iin, and afterwards in a pamphlet of Dr. Pat-

erson, of Dublin.

13. Ascites. The dropfy of the cavity of the abdomen is known by a tense swelling of the belly; which does not found on being struck like the tympany; and in which a sluctuation can be readily perceived by applying one hand expanded on one side, and striking the tumour on the other.

Effusions of water into large cavities, as into that of the abdomen or thorax, or into the ventricles of the brain or pericardium, are more difficult to be re-absorbed, than the effusion of fluids into the cellular membrane; because one part of this ex-

tensive sponge-like system of cells, which connects all the solid parts of the body, may have its power of absorption invariant, at the same time that some other part of it may still retain that power, or perhaps possess it in an increased degree; and as all these cells communicate with each other, the fluid, which abounds in one part of it, can be transferred to another, and thus be reabsorbed into the circulation.

In the afcites, cream of tartar has fometimes been attended with fuccess; a dram or two drams are given every hour in a morning till it operates, and this is to be repeated for several days; but the operation of tapping is generally applied to at last. Dr. Sims, in the Memoirs of the Medical Society of London, Vol. III. has lately proposed, what he believes to be a more successful method of performing this operation, by making a puncture with a lancet in the scar of the navel, and leaving it to discharge itself gradually for several days, without introducing a canula, which he thinks injurious, both on account of the too sudden emission of the sluid, and the danger of wounding or stimulating the viscera. This operation I have twice known performed with less inconvenience, and I believe with more benefit to the patient, than the common method.

After the patient has been tapped, some have tried injections into the cavity of the abdomen, but hitherto I believe with ill event. Nor are experiments of this kind very promising of success. First, because the patients are generally much debilitated, most frequently by spirituous potation, and have generally a disease of the liver, or of other viscera. And secondly, because the quantity of inflammation, necessary to prevent suture secretion of mucus into the cavity of the abdomen, by uniting the peritoneum with the intestines or mesentery, as happens in the cure of the hydrocele, would I suppose generally destroy the patient, either immediately, or by the consequence of such adhesions.

This however is not the case in respect to the dropsy of the

ovarium, or in the hydrocele.

14. Hydrops thoracis. The dropfy of the cheft commences with lofs of flesh, cold extremities, pale countenance, high coloured urine in small quantity, and general debility, like many other dropsies. The patient next complains of numbness in the arms, especially when elevated, with pain and difficulty of swallowing, and an absolute impossibility of lying down for a few minutes, or with sudden starting from sleep, with great difficulty of breathing and palpitation of his heart. It is often consounded with analarca pulmonum, which see.

The numbres of the arms is probably owing more frequently to the increased action of the pectoral muscles in respiration, Vol. II.

whence they are lefs at liberty to perform other offices, than to the connexion of nerves mentioned in Sect. XXIX. 5. 2. The difficulty of swallowing is owing to the compression of the cesophagus by the lymph in the chest; and the impossibility of breathing in a horizontal posture originates from this, that if any parts of the lungs must be rendered useless, the inability of the extremities of them must be less inconvenient to respiration; since if the upper parts or larger trunks of the air-vessels should be rendered useless by the compression of the accumulated lymphs, the air could not gain admitance to the other parts, and the animal must immediately perish.

If the pericardium is the principal feat of the disease, the pulse is quick and irregular. If only the cavity of the thorax is

hydropic, the pulse is not quick nor irregular.

If one fide is more affected than the other, the patient leans

most that way, and has more numbness in that arm.

The hydrops thoracis is diftinguished from the anafarca pulmonum, as the patient in the former cannot lie down half a minute; in the latter the difficulty of breathing, which occasions him to rife up, comes on more gradually; as the transition of the lymph in the cellular membrane from one part to another of it is flower, than that of the effused lymph in the cavity of the cheft.

The hydrops thoracis is often complicated with fits of convulive breathing; and then it produces a difease for the time very similar to the common periodic asthma, which is perhaps owing to a temporary anasarca of the lungs; or to an impaired venous absorption in them. These exacerbations of difficult breathing are attended with cold extremities, cold breath, cold tongue, upright posture with the mouth open, and a defire of cold air, and a quick, weak, intermittent pulse, and contracted hands.

These exacerbations recur fometimes every two or three hours, and are relieved by opium, a grain every hour for two or three doses, with ether about a dram in cold water; and seem to be a convulsion of the muscles of respiration induced by the pain of the dyspnea. As in Class III. r. 1. 9.

M. M. A grain of dried fquill, and a quarter of a grain of blue vitriol every hour for fix or eight hours, unless it vomit or purge. A grain of opium. Blisters. Calomel three grains every third day, with infusion of senna. Bark. Chalybeates.

Puncture in the fide.

Can the fluctuation in the cheft be heard by applying the ear to the fide, as Hippocrates afferts? Can it be felt by the hand or by the patient before the disease is too great to admit of cure by

the paracentess? Does this dropfy of the cheft often come on after peripheumony? Is it ever cured by making the patient lock by tincture of digitalis? Could it be cured, if on one fide only, by the operation of puncture between the ribs, and afterwards by inflaming the cavity by the admission of air for a time, like the cure of the hydrocele; the pleura afterwards adhering wholly to that lobe of the lungs, so as to prevent any future effusion of mucus?

I fulpect the anafarca of the lungs, as well as the hydrops thoracis, to be most frequently diseases of those membranes onky, and not to depend on the general paralysis of the absorbent fyitem; and that they are then not accompanied with swelled legs, till the patient becomes univerfally weak; and that they have for their cause a rheumatic or gouty peripneumony or pleurify; that is, that the lungs or pleura have been inflamed from their fympathy with fome other vifcus, and have deposited much coagulable lymph on the furface of their inflamed membranes, which could not readily become absorbed, and has thus caused the dropfy of the cavity of the cheft, like the coagulable lymph or chalky matter left after the gout and rheumatism in other parts; or that the cellular membrane of the lungs becomes filled with a fluid from the prefent inaction of their absorbent vesfels, which had previously been excited too violently; and that the anafarca of the lungs is thus produced like the anafarca which, frequently in weak constitutions, exists after the gout in the feet and knees, and after rheumatic inflammations of the joints. See Peripneumonia, Class II. 1. 2. 4. whence it appears. why the hydrops thoracis and anafarca pulmonum fo generally occur in goury constitutions.

15. Hydrops ovarii. Dropfy of the ovary is another encyfted dropfy, which feldom admits of cure. It is diftinguished from ascites by the tumour and pain, especially at the beginning, occupying one fide, and the fluctuation being less distinctly perceptible. When it happens to young subjects it is less liable to be mittaken for ascites. It affects women of all ages, either married or virgins; and is produced by cold, fear, hunger, bad food, and other debilitating causes. I saw an elegant young lady, who was shortly to have been married to a sensible man, with great prospect of happiness; who, on being overturned in a chaife in the night, and obliged to walk two or three miles in wet, cold, and darkness, became much indisposed, and gradually afflicted with a swelling and pain on one side of the abdomen; which terminated in a dropfy of the ovary, and destroyed her in two or three years. Another young woman I recollect feeing, who was about seventeen, and being of the very inferior class of people, feemed to have been much weakened by the hardship of a cold floor, and little or no bed, with bad food; and who to thefe evils had to bear the unceasing obloquy of her neighbors,

and the perfecution of parish officers.

The following is abstracted from a letter of my friend Mr. Power, furgeon, at Bofworth in Leicestershire, on examining the body of an elderly lady who died of this disease, March 20. "On opening the abdomen I found a large cyst attached to the left ovarium by an elastic neck as thick as the little finger, and fo callous as not to admit of being feparated by fciffars without confiderable difficulty. The fubitance of the cyst had an appearance much refembling the gravid uterus near the full period of gestation, and was as thick. It had no attachment to the peritoneum, or any of the vifcera, except by the hard callous neck I have mentioned; fo that the blood must with difficulty have been circulated through it for some time. Its texture was extremely tender, being eafily perforated with the finger, was of a livid red colour, and evidently in a sphacelated state. It contained about two gallons of a fluid of the colour of port wine, without any greater tenacity. It has fallen to my lot to have opened two other patients, whose deaths were occasioned by encyfted dropfy of the ovarium. In one of thefe the ovarium was much enlarged with eight or ten cysts on its surface, but there was no adhesion formed by any of the cysts to any other part; nor had the ovarium formed any adhesion with the peritoneum, though in a very difeafed state. In the other the difeafe was more fimple, being only one cyft, without any attachment but to the ovarium.

" As the ovarium is a part not necessary to life, and dropsies of this kind are so generally fatal in the end, I think I shall be induced, notwithstanding the hazard attending wounds, which penetrate the cavity of the abdomen, to propose the extirpation of the difeafed part in the first case, which occurs to me, in which I can with precision fay, that the ovarium is the feat of the disease, and the patient in other respects tolerably healthy; as the cavity of the abdomen is often opened in other cases without bad confequences."

An argument, which might further countenance the operation thus proposed by Mr. Power, might be taken from the disease frequently affecting young persons; from its being generally in these subjects local and primary; and not like the ascites, produced or accompanied with other difeafed vifcera; and laftly, as it is performed in adult quadrupeds, as old fows, with

fafety, though by awkward operators.

16. Anafarca pulmenum. The dropfy of the cellular mem-

brane of the lungs is usually connected with that of the other parts of the fystem. As the cells of the whole cellular membrane communicate with each other, the mucilaginous sluid, which remains in any part of it for want of due absorption, sinks down to the most depending cells; hence the legs swell, though the cause of the ditease, the deficiency of absorption, may be in other parts of the fystem. The lungs however are an exception to this, since they are suspended in the cavity of the thorax, and

have in confequence a depending part of their own.

The anafarca of the lungs is known by the difficulty of refpiration accompanied with fwelled legs, and with a very irregular pulse. This last circumstance has generally been ascribed to a dropfy at the same time existing in the pericardium, but is more probably owing to the difficult passage of the blood through the lungs; because I found on diffection, in one instance, that the most irregular pulse, which I ever attended to, was owing to very extensive adhesion of the lungs; insomuch that one lobe intirely adhered to the pleura; and secondly, because this kind of cropsy of the lungs is so certainly removed for a time along with

the anafarca of the limbs by the use of digitalis.

This medicine, as well as emetic tartar, or fquill, when given fo as to produce fickness, or nausea, or perhaps even without producing either in any perceptible degree, by affecting the lymphatics of the stomach, so as either to invert their motion, or to weaken them, increases by reverse sympathy the action, and confequent absorbent power of these lymphatics, which open into the cellular membrane. But as these medicines seldom succeed in producing an absorption of those sluids, which stagnate in the larger cavities of the body, as in the abdomen, or chest, and do generally succeed in this difficulty of breathing with irregular pulse above described, I conclude that it is not owing to an effusion of lymph into the pericardium, but simply to an analarca of the lungs.

M. M. Digitalis. See Art. V. 2. 1. 2. and IV. 2. 3. 7. Tobacco. Squill. Emetic tartar (antimonium tartarizatum). Then Sorbentia. Chalybeates. Opium half a grain twice a day. Raifin wine and water, or other wine and water, is preferred to the spirit and water, which these patients have general-

ly been accustomed to.

I have feen two cases, which were esteemed to be hydrothorax, but which I believed to be anasarca pulmonum, though they were attended with irregular pulse; for I do not understand, why an irregularity of pulse should be occasioned by water in the pericardium any more than by water in the lungs, or by any other obstruction to the circulation. See Class IV. 2. 1. 18.

Pulsus intermittens, and Palpitatio cordis.

In both these cases the patients could not sleep above one minute at a time; which I ascribed to the debility of the action of the heart compared with the resistance to the circulation, and that some voluntary exertion became necessary to carry on the circulation, which does not exist in sleep. See Class I. 2. 1. 3. Somnus interruptus.

These two cases of patients about fixty years of age are here mentioned from a curious circumstance, that both the patients became in some degree infane after being relieved by the tincture of digitalis taken to the quantity of thirty drops three or four times a day for two or three days; and remained in a flight degree of infanity for some months, and then as this increase of voluntary exertion ceased, they again became afflicted with the anafarca pulmonum, and fwelling of the legs, and this repeatedly for two or three years. I have before feen a common anafarca repeatedly cured by infanity for a year or two, and two fevers I have feen attended with great debility cured by the accefs of infanity, which was called delirium by the attendants; and I lately witneffed the prefent cure of what was believed to be confumption by the access of infanity. All which were probably effected by the increased energy of some parts of the fystem owing to the addition of volition to the sensorial powers of irritation or affociation.

The usual cause of anasarca is from a diseased liver, and hence it most frequently attends those, who have drunk much fermented or spirituous liquors; but I suspect that there is another cause of anasarca, which originates from the brain; and which is more certainly satal than that, which originates from a diseased liver. These patients, where the anasarca originates from, or commences in, the brain, have not other symptoms of diseased liver; have less difficulty of breathing at the beginning; and hold themselves more upright in their chair, and in walking. In this kind of dropsy I suspect the digitalis has less or no effect; as it particularly increases the absorption from the lungs.

17. Obefitas. Corpulency may be called anafarca or dropfy of fat, fince it must be owing to an analogous cause; that is, to the deficient absorption of fat compared to the quantity secreted into the cells which contain it. See Class II. 1. 4.

The method of getting free from too much fat without any injury to the constitution, consists, first, in putting on a proper bandage on the belly, so that it can be tightened or relaxed with case, as a tightish under waistcoat, with a double row of buttons. This is to compress the bowels and increase their absorption;

and it thus removes one principal cause of corpulency, which is the loofeness of the skin. Secondly, he should omit one entire meal, as supper; by this long abstinence from food the absorbent system will act on the mucus and fat with greater energy. Thirdly, he should drink as little as he can with ease to his senfations; fince, if the absorbents of the stomach and bowels supply the blood with much, or perhaps too much, aqueous fluid, the absorbents of the cellular membrane will act with less energv. Fourthly, he should use much falt or salted meat, which will increase the perspiration and make him thirsty; and if he bears this thirst, the absorption of his fat will be greatly increased, as appears in fevers and dropfies with thirst; this I believe to be more efficacious than foap. Fifthly, he may use aerated alkaline water for his drink, which may be supposed to render the fat more fluid, -or he may take foap in large quantities, which will be decomposed in the stomach. Sixthly, short rest, and constant exercise.

Vinegar has been said to reduce corpulency, but as it contains much vinous spirit, it may injure the general health without previously inducing leanness. Perhaps crystals of tartar

might fucceed better used daily in water at meals.

The most efficacious method of reducing the quantity of the fat I suspect may be by the use of the tincture of digitalis in small quantity, as twenty or thirty drops twice a day, as directed in Article IV. 2. 3. 7. As the effect of this medicine, when given in greater quantity, as in forty drops twice or thrice a day in hydrothorax or general anasarca, evidently consists in weakening the natural actions of the stomach, perhaps by previously stimulating that viscus too violently; in consequence the heart and arteries act less powerfully from their sympathy with the stomach; and the capillary vessels, and absorbents, act more powerfully in consequence of the less expenditure of sensorial power by the inert action of the heart and arteries; and will consequently absorb the accumulated fat from the cellular membrane, as explained in Supplement I. 12. 10.

18. Splenis tumor. Swellings of the fpleen, or in its vicinity, are frequently preceived by the hand in intermittents, which are called Ague-cakes, and feem owing to a deficiency of absorption

in the affected part.

Mr. Y—, a young man about twenty-five years of age, who lived intemperately, was feized with an obstinate intermittent, which had become a continued fever with strong pulse, attended with daily remission. A large hard tumour on the less side, on the region of the spleen, but extending much more downward, was so distinctly preceptible, that one seemed to get

one's

one's fingers under the edge of it, much like the feel of the brawn or shield on a boar's shoulder. He was repeatedly bled, and purged with calomel, had an emetic, and a blister on the part, without diminishing the tumour; after some time he took the Peruvian bark, and slight doses of chalybeates, and thus became free from the fever, and went to Bath for several weeks, but the tumour remained. This tumour I examined every four or five years for above thirty years. His countenance was pale, and towards the end of his life he suffered much from ulcers on his legs, and died about fixty, of general debility; like many others who live intemperately in respect to the ingurgitation of fermented or spirituous liquois.

As this tumour commenced in the cold fit of an intermittent fever, and was not attended with pain, and continued fo long without endangering his life, there is reason to believe it was simply occasioned by deficient absorption, and not by more energetic action of the vessels which constitute the spleen. See

Class II. 1. 2. 13.

M. M. Venefection. Emetic, cathartic with calomel; then

forbentia, chalybeates, Peruvian bark.

19. Genu tumor albus. White fwelling of the knee, is owing to deficient abforption of the lymphatics of the membranes including the joint, or capfular ligaments, and fometimes perhaps of the gland which fecretes the fynovia; and the ends of the bones are probably affected in confequence.

I faw an inftance, where a caustic had been applied by an empyric on a large white swelling of the knee, and was told, that a fluid had been discharged from the joint, which became an-

chylosed, and healed without loss of the limb.

M. M. Repeated blifters on the part early in the difease are faid to cure it by promoting absorption; saturnine solutions externally are recommended. Bark, animal charcoal, as burnt sponge, opium in small doses. Friction with the hand. Four or six leeches applied on or beneath the knee alternately with the blifters, and a cupping glass put over the wounds made by the leeches are much recommended.

20. Bronchocele. Swelled throat. An enlargement of the thyroid glands, faid to be frequent in mountainous countries, where river water is drunk, which has its fource from diffolving fnows. This idea is a very ancient one, but perhaps not on that account to be the more depended upon, as authors copy one another. Tumidum guttur quis miratur in Alpibus, feems to have been a proverb in the time of Juvenal. The inferior people of Derby are much subject to this difease, but whether more so than other populous towns, I can not determine; certain

it is, that they chiefly drink the water of the Derwent, which arifes in a mountainous country, and is very frequently blackened as it passes through the morasses near its source; and is generally of a darker colour, and attended with a whiter soam, than the Trent, into which it salls; the greater quantity and whiteness of its froth I suppose may be owing to the viscidity communicated to it by the colouring matter. The lower parts of the town of Derby might be easily supplied with spring water from St. Alkmond's well; or the whole of it from the abundant springs near Bowbridge: the water from which might be conveyed to the town in hollow bricks, or clay-pipes, at no very great expence, and might be received into frequent reservoirs with pumps to them; or laid into the houses.

M. M. Twenty grains of burnt sponge with ten of nitre made with mucilage into lozenges, and permitted to dissolve slowly under the tongue twice a day, is afferted to cure in a few months; perhaps other animal charcoal, as candie-snuffs, might do the

fame.

I have directed in the early state of this disease a mixture of common salt and water to be held in the mouth, particularly under the tongue, for a few minutes, four or six times a day for many weeks, which has sometimes succeeded, the salt and water is then spit out again, or in part swallowed. Externally vinegar of squills has been applied, or a mercurial plaster, or somentations of acetated ammoniac; or ether. Some empyrics have applied caustics on the bronchocele, and sometimes, I have been told, with success; which should certainly be used where there is danger of suffocation from the bulk of it. One case I saw, and one I was well informed of, where the bronchocele was cured by burnt sponge, and a hectic sever supervened with colliquative sweats; but I do not know the sinal event of either of them.

De Haen affirms the cure of branchocele to be effected by flowers of zinc, calcined egg-shells, and scarlet-cloth burnt together in a close crucible, which was tried with success, as he affured me, by a late lamented physician, my friend, Dr. Small of Birmingham; who to the cultivation of modern sciences added the integrity of ancient manners; who in clearness of head, and benevolence of heart, had sew equals, perhaps no superiors.

21. Scrofula. King's evil is known by tumours of the lymphatic glands, particularly of the neck. The upper lip, and division of the nostrils are swelled, with a florid countenance, a smooth skin, and a tumid abdomen. Cullen. The absorbed sluids in their course to the veins in the scrofula are arrested in the lymphatic or conglobate glands; which swell, and after a great length of time, inflame and suppurate. Materials of a peculiar

Vol. II. kind,

kind, as the variolous and venereal matter, when abforbed in a wound, produce this torpor, and confequent inflammation of those lymphatic glands, where they first arrive, as in the axilla and groin. There is reason to suspect, that the tonsils frequently become inflamed, and suppurate from the matter absorbed from carious teeth; and I saw a young lady, who had both the axillary glands swelled, and which suppurated; which was believed to have been caused by her wearing a pair of new green gloves for one day, when she had perspired much, and was much exhausted and satigued by walking; the gloves were probably dyed in a solution of verditer.

These indolent tumours of the lymphatic glands, which conflitute the scrofula, originate from the inirritability of those glands; which therefore sooner fall into torpor after having been stimulated too violently by some poisonous material; as the muscles of enseebled people sooner become fatigued, and cease to act, when exerted, than those of stronger ones. On the same account these scrofulous glands are much longer in acquiring increase of motion, after having been stimulated into inactivity, and either remain years in a state of indolence, or suppurate with difficulty, and sometimes only partially.

The difference between fcrofulous tumours, and those before described, consists in this; that in those either glands of different kinds were diseased, or the mouths only of the lymphatic glands were become torpid; whereas in scrofula the conglobate glands themselves become tumid, and generally suppurate after a great length of time, when they acquire new sensibility.

See Sect. XXXIX. 4. 5.

These indolent tumours may be brought to suppurate sometimes by passing electric shocks through them every day for two or three weeks, as I have witnessed. It is probable, that the alternate application of snow or iced water to them, till they become painfully cold, and then of warm slannel or warm water, frequently repeated, might restore their irritability by accumulation of sensorial power; and thence either facilitate their dispersion, or occasion them to suppurate. See Class II. 1. 4. 13.

This difease is very frequent amongst the children of the poor in large towns, who are in general ill sed, ill lodged, and ill clothed; and who are further weakened by eating much salt with their scanty meal of insipid vegetable food, which is seldom of better quality than water gruel, with a little coarse bread in it. See diarrheea of infants, Class I. 1. 2. 5. Serofulous ulcers are difficult to heal, which is owing to the desciency of absorption on their pale and slabby surfaces, and to the general inirritability of the system. See Class I. 1. 3. 13.

M. M. Plentiful

M. M. Plentiful diet of flesh meat and vegetables with small beer. Opium, from a quarter of a grain to half a grain twice a day. Sorbentia. Tincture of digitalis, thirty drops twice a day. Externally fea-bathing, or bathing in falt and water, one pound to three gallons, made warm. The application of Peruvian bark in fine powder, feven parts, and white lead (ceruffa), in fine powder one part, mixed together and applied on the ulcers in dry powder, by means of lint and a bandage, to be renewed every day. Or very fine powder of calamy alone, lapis calaminaris. If powder of manganese? See Class II. 1. 4. 13.

22. Scirrbus. After the absorbent veins of a gland cease to perform their office, if the feeerning arteries of it continue to act some time longer, the fluids are pushed forwards, and stagnate in the receptacles or capillary vessels of the gland; and the thinner part of them only being refumed by the absorbent system of the gland, a hard tumour gradually fucceeds; which continues like a lifeless mass, till from some accidental violence it gains fenfibility, and produces cancer, or suppurates. Of this kind are the scirrhus glands of the breasts, of the lungs, of the mesentery, and the fcrofulous tumours about the neck and the bron-

Another feat of scirrhus is in the membranous parts of the fystem, as of the rectum intestinum, the urethra, the gula or throat; and of this kind is the veruca or wart, and the clavus pedum, or corus on the toes. A wen fometimes arises on the back of the neck, and sometimes between the shoulders; and by diftending the tendinous faicia produces great and perpetual pain.

M. M. Mercurial ointment. Cover the part with giled filk. Extirpation. Electric shocks through the tumour. An issue into the substance of the wen. Opium. Ether externally.

23. Scirrhus recti intestini. Scirrhus of the rectum. A scirrhus frequently affects a canal, and by contracting its diameter becomes a painful and deplorable difease. The canals thus obstructed are the rectum, the urethra, the throat, the gall-ducts, and probably the excretory ducts of the lymphatics, and of oth-

er glands.

The scirrhus of the rectum is known by the patient having pain in the part, and being only able to part with liquid feces, and by the introduction of the finger; the fwelled part of the testine is fometimes protruded downwards, and hangs like a valve, fmooth and hard to the touch, with an aperture in the centre of it. See a paper on this subject by J. Sherwin. Memoirs of a London Medical Society, Vol. II. p. 9.

M. M. To take but little folid food. Aperient medicines.

Introduce

Introduce a candle fmeared with mercurial ointment. Spongetent. Clyfters with forty drops of laudanum. Introduce a leathern canula, or gut, and then either a wooden maundril, or blow it up with air, so as to distend the contracted part as much as the patient can bear. Or spread mercurial plaster on thick fost leather, and roll it up with the plaster outwards to any thickness and length, which can be easily introduced and worn; or two or three such pieces may be introduced after each other. The same may be used to compress bleeding internal piles. See Class I. 2. 1. 6. Rub mercurial ointment on the sphincler and every night for a fortnight.

May not this difease be cured by lunar caustic applied on the end of a pessary or bougie, in the same manner as used by J. Hunter, and since by Mr. E. Home, in strictures of the urethra; when, on introducing the singer, a kind of membranous valve can be distinguished rather than an extensive scirrhus or induration.

See the next article.

24. Scirrhus urethra. Scirrhus of the urethra. The paffage becomes contracted by the thickened membrane, and the urine is forced through with great difficulty, and is thence liable to diftend the canal behind the stricture; till at length an aperture is made, and the urine forces its way into the cellular membrane, making large sinuses. This situation sometimes continues many months, or even years, and so much matter is evacuated after making water, or at the same time, by the action of the muscles in the vicinity of the sinuses, that it has been mistaken for an increased secretion from the bladder, and has been erroneously termed a catarrh of the bladder. See a paper by Dr. R. W. Darwin in the Medical Memoirs.

M. M. Diftend the part gradually by catgut bougies, which by their compression will at the same time diminish the thickness of the membrane, or by bougies of elastic gum, or of horn boiled foft. The patient should gain the habit of making water slowly, which is a matter of the utmost consequence, as it prevents the distention and consequent rupture, of that part of the urethra, which is between the stricture and the neck of the bladder.

When there occurs an external ulcer in the perinæum, and the urine is in part discharged that way, the disease cannot be mistaken. Otherwise, from the quantity of matter, it is generally supposed to come from the bladder, or prostate gland; and the urine, which escapes from the ruptured urethra, mines its way amongst the muscles and membranes, and the patient dies tabid, owing to the want of an external orifice to discharge the matter. See Class II. 1. 4. 11.

Mr. Home has published a very ingenious and useful work, enaitled, a Differtation on Strictures of the Urethra, in which he has recorded many eases successfully treated by lunar caustic, inserted in the end of a bougie, and applied to the contracted part of the urethra, so as to destroy the stricture.

From the form of the cavity of the urethra, taken by injecting wax into it, there appears naturally to exist a kind of valve immediately behind the bulb of the urethra, which when the penis is erect, thuts up the orifice, and prevents the regurgitation of the semen into the bladder during the action of the accelerator muscles in the act of its expulsion; and this natural constriction

or valve appears generally to be the first feat of stricture.

Above the bulb, about two or three inches from the orifice of the glans, the cavity of the urethra appears also lessend; and in some cases the orifice of the very extremity appears less than other parts of the canal; these parts are therefore more contracted during the emission seminis, and add to its velocity at its exit; and are thence more liable to scirrhosity or stricture. And by some observations, Mr. Home has shewn, that a sympathy exists between the strictures of these parts; and that the more forward strictures are frequently produced in consequence of that behind the bulb; and finds it necessary to destroy them all, by frequent application of the caustic.

By the use of which, (which was first proposed by Wiseman, first applied by John Hunter, and so greatly improved by Mr. Home) the lives of great numbers are rendered happy, who otherwise gradually perish by a most painful and hopeless malady.

25. Scirrhus Epphagi. A scirrhus of the throat contracts the passage so as to render the swallowing of solids impracticable, and of liquids difficult. It affects patients of all ages, but is probably most frequently produced by swallowing hard angular substances, when people have lost their teeth; by which this membrane

is over-distended, or torn, or otherwise injured.

M. M. Put milk into a bladder tied to a canula or catheter; introduce it past the stricture, and press it into the stomach. Distend the stricture gradually by a sponge-tent sastened to the end of whalebone, or by a plug of wax, or a spermaceti candle, about two inches long; which might be introduced, and lest there with a string only fixed to it to hang out of the mouth, to keep it in its place, and to retract it by occasionally; for which purpose the string must be put through a catheter or hollow probang, when it is to be retracted. Or lastly, introduce a gut fixed to a pipe; and then distend it by blowing wind into it. The swallowing a bullet with a string put through it, to retract it on the exhibition of on emetic, has also been proposed. Ex-

ternally,

ternally, mercurial ointment has been much recommended. Poultice. Oiled filk. Clysters of broth. Warm bath of broth. Transfusion of blood into a vein three or four ounces a day? See Class III. 1. 15.

I directed a young woman, about twenty-two years of age. to be fed with new milk put into a bladder, which was tied to a catheter, and introduced beyond the stricture in her throat: after a few days, her spirits funk, and she refused to use it further, and died. Above thirty years ago, I proposed to an old gentleman, whose throat was entirely impervious, to supply him with a few ounces of blood daily from an ass, or from the human animal, who is still more patient and tractable, in the following manner: To fix a filver pipe about an inch long to each extremity of a chicken's gut, the part between the two filver ends to be measured by filling it with warm water; to put one end into the vein of a person hired for that purpose, so as to receive the blood returning from the extremity; and when the gut was quite full, and the blood running through the other filver end, to introduce that end into the vein of the patient upwards towards the heart, fo as to admit no air along with the blood. And lastly, to support the gut and silver ends on a water-plate, filled with water of ninety-eight degrees of heat, and to measure how many ounces of blood was introduced by passing the finger, fo as to compress the gut, from the receiving-pipe to the delivering-pipe; and thence to determine how many gut-fulls were given from the healthy person to the patient. Mr. -- confidered a day on this propofal, and then another day, and at length answered, that "he now found himself near the house of death; and that, if he could return, he was now too old to have much enjoyment of life; and therefore he wished rather to proceed to the end of that journey, which he was now fo near, and which he must at all events soon go, than return for so short a time." He lived but a few days afterwards, and feemed quite careless and easy about the matter. See Suppl. I. 14. 4.

A difficulty of swallowing food, and a rejection soon after, of the whole or a part of it, may be often owing probably to a fort of valve made by a part of the membrane which lines the cesophagus; and may thus resemble strictures of the urethra; which last are so frequently cured by the nice application of lunar caustic, as described by Mr. Everard Home, in his Treatise on Strictures of the Urethra. Suppose a thick bougie, made of linen spread with adhesive plaster, and rolled up, was armed at the end with a bit of lunar caustic, with which the stricture of the cesophagus could be touched repeatedly, till an unarmed bougie could be passed readily into the stomach? Could such a valve be

burft,

burst, or inverted, by pouring a pound or two of crude mercury

into the cefophagus?

26. Lacterum inirritabilitas. Inirritability of the lacteals is described in Sect. XXVIII. under the name of paralysis of the lacteals; but as the word paralysis has generally been applied to the disobedience of the muscles to the power of volition, the name is here changed to inirritability of the lacteals, as more characteristic of the disease.

27. Lymphaticorum inirritabilitas. The inirritability of the cellular and cutaneous lymphatics is described in Sect. XXIX. 5.

1. and in Class I. 2. 3. 16. The inirritability of the cutaneous lymphatics generally accompanies anasarca, and is the cause of the great thirst in that malady. At the same time, the cellular lymphatics act with greater energy, owing to the greater derivation of sensorial power to them, in consequence of the less expenditure of it by the cutaneous ones; and hence they absorb the fat, and mucus, and also the thinner parts of the urine. Whence the great emaciation of the body, the muddy sediment, and the small quantity of water in this kind of dropsy.

ORDO II.

Decreased Irritation.

GENUS IV.

With decreased Actions of other Cavities and Membranes.

Many of the diseases of this genus are attended with pains and with cold extremities, both which cease on the exhibition of wine or opium; which shews, that they originate from deficient action of the affected organ. These pains are called nervous or spasmodic, are not attended with sever, but are frequently succeeded by convulsions and madness; both which belong to the class of volition. Some of them return at periods, and when these can be ascertained, a much less quantity of opium will prevent them, than is necessary to cure them, when they are begun; as the vessels are then torpid and inirritable from the want of sensorial power, till by their inaction it becomes again accumulated.

Our organs of fense, properly so called, are not liable to pain from the absence of their appropriated stimuli, as from darkness or silence; but the other senses, which may be more properly called appetites, as those by which we perceive heat, hunger, thirst, lust, want of fresh air, are affected with pain from the defect or absence of their accustomed stimuli, as well as with pleasure by the possession of them; it is probable that some of our glands, the sense or appetite of which requires or receives something from the circulating blood, as the pancreas, liver, testes, prostate gland, may be affected with aching or pain, when they

cannot acquire their appropriated fluid.

Wherever this defect of stimulus occurs, a torpor or inaction of the organ ensues, as in the capillaries of the skin, when exposed to cold; and in the glands, which secrete the gastric juice, when we are hungry. This torpor however, and concomitant pain, which are at first owing to defect of stimulus, are afterwards induced by other affociations or catenations, and consti-

tute the beginning of ague-fits.

It must be further observed, that in the diseases of pain without sever, the pain is frequently not felt in the part where the cause of the disease resides; but is induced by sympathy with a distant part, the irritability or sensibility of which is greater or less than its own. Thus a stone at the neck of the bladder, if its stimulus is not very great, only induces the pain of strangury at the glans penis. If its stimulus be greater, it then induces pain at the neck of the bladder. The concretions of bile, which are protruded into the neck of the gall-bladder, when the disease is not very great, produce pain at the other extremity of the bileduct, which enters the duodenum immediately under the pit of the stomach; but, when the disease is great from the largeness of the bile-stone, the pain is felt in the region of the liver at the neck of the gall-bladder.

It appears from hence, that the pains enumerated in this genus are consequences of the inactivity of the organ; and, as they do not occasion other diseases, should be classed according to their proximate cause, which is, desective irritation; there are nevertheless other pains from desect of stimulus, which produce convulsions, and belong to Class III. 1. 1.; and others, which produce pains of some distant part by association, and belong to

Class IV. 2. 2.

SPECIES.

r. Sitis. Thirst. The senses of thirst and of hunger seem to have this connexion, that the former is situated at the upper end, and the latter at the lower end of the same canal. One about the pharinx, where the essophagus opens into the mouth, and the other about the cardia ventriculi, where it opens into the stomach. The extremities of other canals have been shewn to possess correspondent sensibilities, or irritabilities, as the two ends of the urethra, and of the common gall-duct. See IV. 2. 2.

and 4.

The membrane of the upper end of the gullet becomes torpid, and confequently painful, when there is a deficiency of aqueous fluid in the general fystem; it then wants its proper stimulus. In the same manner a want of the stimulus of more solid materials at the other end of the canal, which terminates in the stomach, produces hunger; as mentioned in Sect. XIV. 8. The proximate causes of both of them therefore consist in deficient irritation, when they are confidered as pains; because these pains are in consequence of the inactivity of the organ, according to the fifth law of animal causation. Sect. IV. 5. But when they are confidered as defires, namely, of liquid or folid aliment, their proximate cause confists in the pain of them, according to the fixth law of animal causation. So the proximate cause of the pain of coldness is the inactivity of the organ, and perhaps the consequent accumulation of sensorial power in it; but the pain itself or the consequent volition, is the proximate cause of the VOL. II.

fluddering and gnashing the teeth in cold fits of intermittent fevers. See Class I. 2. 2. 1.

Thirst may be divided into two varieties, alluding to the remote cause of each, and may be termed sitis calida, or warm thirst, and sitis frigida, or cold thirst. The remote cause of the former arises from the dissipation of the aqueous parts of our sluids by the increased secretion of perspirable matter, or other evacuations. And hence it occurs in hot sits of sever, and after taking much wine, opium, spice, salt, or other drugs of the Art. incitantia or secennentia. The thirst, which occurs about three hours after eating a couple of red herrings, to a person unaccustomed to salted meat, is of this kind; the increased action of the cutaneous vessels dissipates so much of our sluids by insensible perspiration, as to require above two quarts of water to restore the fluidity of the blood, and to wash the salt out of the system. See Art. III. 2. 1.

M. M. Cold water. Vegetable acids. Warm bath.

The remote cause of sitis frigida, or cold thirst, is owing to the inaction of the cutaneous, pulmonary, urinary, and cellular absorbents; whence the blood is deprived of the great supply of moisture which it ought to receive from the atmosphere, and from the cells of the cellular membrane, and from other cysts; this cause of thirst exists in dropsies, and in the cold sits of intermittents. The desire of sluids, like that of solids, is liable to acquire periods, and may therefore readily become diseased by indulgence in liquids grateful to the palate.

Of diseased thirst, the most common is either owing to desect of the action of the numerous absorbent vessels on the neck of the bladder, in which the patient makes much paleish water; or to the desective absorption of the skin and lungs, in which the patient makes but little water, and that high-coloured, and with sediment. In both the tongue and lips are liable to become very dry. The former in its greatest degree attends diabetes, and the

latter anasarca.

M. M. Warm water, warm wine, warm bath. Opium.

Cold bath. Iced water. Lemonade. Cyder.

2. Ejuries. Hunger has been fancifully ascribed to the sides of the stomach rubbing against each other, and to the increased acidity of the gastric juice corroding the coats of it. If either of these were the cause of hunger, inflammation must occur, when they had continued some time; but, on the contrary, coldness not heat is attendant on hunger; which evinces, that like thirst it is owing to the inactivity of the membrane, which is the seat of it; while the abundant nerves about the cardia ventriculi,

and the pain of hunger being felt in that part, gives great reason

to conclude, that it is there fituated.

The fense of hunger as well as of thirst, is liable to acquire habits in respect to the times of its returning painfulness, as well as in respect to the quantity required to satisfie its appetency, and hence may become diseased by indulgence, as well as by want of its appropriate stimulus. Those who have been accustomed to distend their stomach by large quantities of animal and vegetable food, and much potation, find a want of distention, when the stomach is empty, which occasions saintness, and is mistaken for hunger, but which does not appear to be the same sensation. I was well informed, that a woman near Litchfield, who eat much animal and vegetable food for a wager, assimated, that since distending her stomach so much, she had never selt herself satisfied with food; and had in general taken twice as much at a meal, as she had been accustomed to, before she eat so much for a wager.

3. Nausea sieca. Dry nausea. Consists in a quiescence or torpor of the mucous or falivary glands, and precedes their inverted motions, described in nausea humida, Class I. 3. 2. 3. In the same manner as siekness of the stomach is a quiescence of that organ preceding the action of vomiting, as explained in Sect. XXXV. 1. 3. This is sometimes induced by disagreeable drugs held in the mouth, at other times by disgustful ideas, and at other times by the association of these actions with those of the stomach; and thus according to its different proximate causes may belong to this, or to the second, or to the fourth

class of diseases.

M. M. Lemonade. Tasteful food. A blister. Warm bath.

4. Egritudo ventriculi. Sickness of stomach is produced by the quiescence or inactivity of that organ, as is explained in Sect. XXXV. 1. 3. It consists in the state between the usual peristaltic motions of that organ, in the digestion of our aliment and the retrograde motions of it in vomiting; for it is evident, that the direct motions of it from the cardia to the pylorus must stop, before those in a contrary direction can commence. This sickness, like the nausea above described, is sometimes produced by disgustful ideas, as when nasty objects are seen, and nasty stories related, as well as by the exhaustion of the sensorial power by the stimulus of some emetic drugs, and by the defect of the production of it, as in ensembled drunkards.

Sickness may likewise consist in the retrograde motions of the lymphatics of the stomach, which regurgitate into it the chyle or lymph, which they have lately absorbed, as in Class I. 3. 2. 3. It is probable, that these two kinds of sickness may be different sen-

fations.

fations, though they have acquired but one name; as one of them attends hunger, and the other repletion; though either of them may possibly be induced by affociation with nauseous ideas.

M. M. A blifter on the back. An emetic. Opium. Crude mercury. Covering the head in bed. See Sect. XXV. 16. Class

IV. 1. 1. 2, and 3.

5. Cardialgia. Heartburn originates from the inactivity of the stomach, whence the aliment, instead of being subdued by digestion, and converted into chyle, runs into sermentation, producing acetous acid. Sometimes the gastric juice itself becomes so acid as to give pain to the upper orifice of the stomach; these acid contents of the stomach, on falling on a marble hearth, have been seen to produce an effery escence on it. The pain of heat at the upper end of the gullet, when any air is brought up from the fermenting contents of the stomach, is to be ascribed to the sympathy between these two extremities of the esophagus rather than to the pungency of the carbonic gas, or fixed air; as the sensation in swallowing that kind of air in water is of a

different kind. See Class I. 3. 1. 3. and IV. 2. 2. 5.

M. M. This difease arising from indigestion is often very pertinacious, and afflicting; and attended with emaciation of the body from want of fufficient chyle. As the faliva swallowed along with our food prevents its fermentation, as appears by the experiments of Pringle and Macbride, some find considerable relief by chewing parched wheat, or maltic, or a lock of wool, frequently in a day, when the pain occurs, and by fwallowing the faliva thus effused; a temporary relief is often obtained from antiacids, or aerated alkaline water, Seltzer water, calcareous earths, alkaline falts made into pills with foap, foap alone, tin, milk, bitters. More permanent use may be had from such drugs as check fermentation, as acid of vitriol; but still more permanent relief from such things as invigorate the digestion, as a blister on the back; a due quantity of vinous spirit and water taken regularly. Steel. Temperance. A fleep after dinner. A waistcoat made fo tight as flightly to compress the bowels and stomach. A flannel shirt in winter, not in summer. A less quantity of potation of all kinds. Ten black pepper-corns swallowed after dinner. Half a grain of opium twice a day, or a grain. The food should consist of such things as do not easily ferment, as flesh, shell-fish, sea-biscuit, toasted cheese. I have seen toasted cheese brought up from the stomach 24 hours after it had been swallowed, without apparently having undergone any chemical change. See Class II. 1. 3. 17. and IV. 1. 2. 13.

It is probable that violent cardialgia is most frequently owing to increase of the quantity or acidity of the gastric juice, rather

than to the acetous acid produced by fermenting aliment; because in violent apepty, as in low severs, and total want of digestion, no such violently strong or painful acidity occurs. See I. 3. 1. 3. See Anorexia II. 2. 2. 1. And secondly, because in all these cases, which have come under my eye, the disease was not increased by vegetable food, or even by acid fruits, when taken in their assal quantity; and I have uniformly observed, that the food which suited the palate, and that water alone, or small wine and water, agreed with these patients better than stronger mixtures of spirit and water, especially when they were more agreeable to the palate.

6. Arthritis Ventriculi. Sickness of the stomach in gouty cases is frequently a consequence of the torpor or inflammation of the liver, and then it continues many days or weeks. But when the patient is seized with great pain at the stomach with the sensation of coldness, which they have called an ice-bolt, this is a primary affection of the stomach, and destroys the patient in a few hours, owing to the torpor or inaction of that viscus so

important to life.

This primary gout of the stomach, as it is a torpor of that viscus, is attended with sensation of coldness, and with real defect of neat in that part, and may thence be distinguished from the pain occasioned by the passage of a gall-stone into the duodenum, as well as by the weak pulse, and cold extremities; to which must be added, that it affects those only, who have been long afflicted with the gout, and much debilitated by its numerous attacks.

M. M. Opium. Vinous fpirit. Volatile alkali. Spice. Warmth applied externally to the ftomach by hot cloths or formentation.

7. Colica flatulenta. The flatulent colic arifes from the too great distention of the bowel by air, and consequent pain. The cause of this disease is the inactivity or want of sufficiently powerful contraction of the coats of the bowel, to carry forwards the gas given up by the sermenting aliment. It is without fever,

and generally attended with cold extremities.

It is distinguished, first, from the pain occasioned by the passage of a gall-stone, as that is felt at the pit of the stomach, and this nearer the navel. Secondly, it is distinguished from the colica faturnina, or colic from lead, as that arising from the torpor of the liver, or of some other viscus, is attended with greater coldness, and with an aching pain; whereas the slatulent colic being owing to distention of the muscles of the bowel, the pain is more acute, and the coldness less. Thirdly, it is distinguished from inflammation of the bowels, or ileus, as perpetual vom-

iting

CLASS I. 2. 4. 8.

iting and fever attend this. Fourthly, it is distinguished from cholera, because that is accompanied with both vomiting and diarrheea. And lastly, from the colica epileptica, or hysteric colic, as that is liable to alternate with convultion, and fometimes with infanity; and returns by periods.

M. M. Spirit of wine and warm water, one spoonful of each. Opium one grain. Spice. Volatile alkali. Warm fomenta-

tion externally. Rhubarb.

8. Colica faturnina. Colic from lead. The pain is felt about the navel, is rather of an aching than acute kind at first, which increases after meals, and gradually becomes more permanent and more acute. It terminates in paralysis, frequently of the muscles of the arm, so that the hand hangs down, when the arm is extended horizontally. It is not attended with fever, or increase of heat. The feat of the disease is not well ascertained; it probably affects some part of the liver, as a pale bluish countenance and deficiency of bile fometimes attend or fucceed it, with confequent anafarca; but it feems to be caused immediately by a torpor of the intestine, whether this be a primary or fecondary affection, as appears from the constipation of the bowels, which attends it; and is always produced in confequence of the great stimulus of lead previously used either internally for a length of time, or externally on a large furface.

A delicate young girl, daughter of a dairy farmer, who kept his milk in leaden cifterns, used to wipe off the cream from the edges of the lead with her finger; and frequently, as the was fond of cream, licked it from her finger. She was feized with the faturnine colic, and femi-paralytic wrifts, and funk from

general debility.

A feeble woman about forty years of age, sprained her ancle, and bruifed her leg and thigh; and applied by ill advice a folution of lead over the whole limb, as a fomentation and poultice for about a fortnight. She was then feized with the colica faturnina, loft the use of her wrifts, and gradually sunk under a

general debility.

There are various means by which lead finds its way into the system; in the cyder counties of this country this disease has been frequently almost epidemic from the use of some lead about their mills, or by the pernicious use of it to correct the acidity of weak cyder. This difease has been so frequent in some of the wine countries, that in France the punishment of death is directed for those, who use lead to destroy the acidity of wine.

There is a bad custom in almost all families and public houses of washing out their bottles by putting a handful of shot corns into them, and by shaking them about forcibly, by which the

lead may in part adhere to the fides of the bottle, and become diffolved in the acid of the wine or cyder. Milk kept in lead is highly pernicious, as in the inflance above related. Nor should coppers for brewing be edged at the top of them with lead, which is frequently done; nor should flesh-meat be salted in leaden cifterns. Another way by which lead is liable to be taken into the stomach is by broth, which is boiled in copper vessels tinned within. Now the lining of thefe veffels confifts, I am well informed, of nearly half lead mixed with the tin; which is very foluble in hot greafe. From this cause those, who live much on foups long boiled, as the French, are perpetually fubject to complaints of the stomach and intestines. When a fauce-pan has been new tinned, if the finger be rubbed hard on it, it becomes black; which is owing to the lead, which is mixed with the tin. Hence the broth for all fick people should be boiled but a short time, and be immediately put into a chinabason.

In an ingenious pamphlet lately published by Mr. Clutterbuck, feveral cases are given of the fuccessful use of mercury in the constipation, colic, and paralysis of the wrists, produced by lead. In some of these patients a drachm of strong mercurial contement was rubbed morning and night on the wrists, till the mouth became fore. In others calomel one grain was given daily with olticini; and in others a quarter of a grain of hydragyrum muriatum, sublimate of mercury, was given three times a day with great apparent advantage. The author ingeniously asks, if small doses of some preparation of lead might not be given internally to counteract the ill effects sometimes believed to result from the too long use of mercury. On the Poison of Lead, Boosey, Lond. See Class III. 2. 1. 4.

The effect of metals in destroying or preventing the acidity of wine or cyder, may be nicely observed in attending to the colour of syrup of violets; which, if it ferments, is changed by the acid thus produced from blue to red: but if it be kept in a tin vessel, this does not occur; as the acid is attracted by the metal producing an oxyde. Other metals are said by M. Guyton, to have the same effect in preserving the colour of syrup

of violets.

M. M. First opium one or two grains, then a cathartic of fenna, jalap, and oil, as soon as the pain is relieved. Oleum ricini. Alum. Oil of almonds. A blitter on the navel. Warm bath. The stimulus of the opium, by restoring to the bowel its natural irritability in this case of painful torpor, assists the action of the cathartic. A clyster of the smoke of tobacco pushed high

up and continued, or repeated frequently for an hour or two, or longer, is faid to remove the pain, and totally to cure the difeafe.

9. Tympanitis. Tympany confifts in an elastic tumor of the abdomen, which founds on being struck. It is generally attended with costiveness and emaciation. In one kind the air is said to exist in the bowels, in which case the tumor is less equal, and becomes less tense and painful on the evacuation of air. In the other kind the air exists in the cavity of the abdomen, and sometimes is in a few days exchanged for water, and the tympany becomes an ascites.

Air may be diffinguished in the fromach of many people by the found on striking it with the fingers, and comparing the found with that of a similar percussion on other parts of the bowels: but towards the end of fevers and especially in the puerperal fever, a differntion of the abdomen by air is generally a fatal symptom, though the ease, and often cheerfulness of the

patient, vainly flatters the attendants.

M. M. In the former case a clyster-pipe unarmed may be introduced, and left some time in the rectum, to take off the resistance of the sphincter, and thus discharge the air, as it is produced from the fermenting or putrefying aliment. For this purpose, in a disease somewhat similar in horses, a perforation is made into the rectum on one side of the sphincter; through which sistual the air, which is produced in such great excess from the quantity of vegetable food which they take, when their digestions are impaired, is perpetually evacuated. In both cases also, balsams, effential oil, spice, bandage on the abdomen, and, to prevent the fermentation of the aliment, acid of vitriol, salivance Class I. 2. 4. 5.

10. Hypochondrias. The hypochondriac disease consists in indigestion and consequent statulency, with anxiety or want of pleasurable sensation. When the action of the stomach and bowels is impaired, much gas becomes generated by the sermenting or putrescent aliment, and to this indigestion is catenated languor, coldness of the skin, and fear. For when the extremities are cold for too long a time in some weak constitutions, indigestion is produced by direct sympathy of the skin and the stomach, with consequent heartburn, and statulency. The same occurs, if the skin be made cold by fear, as in riding over dangerous roads in winter, and hence conversely fear is produced by indigestion or torpor of the stomach by association.

This difease is confounded with the fear of death, which is an infanity, and therefore of a totally different nature. It is also confounded with the hysteric difease, which consists in the

retrograde

retrograde motions of the alimentary canal, and of some parts of

the absorbent system.

The hypochondrialis, like chlorofis, is fometimes attended with very quick pulse; which the patient seems to bear so easily in these two maladies, that if any accidental cough attends them, they may be mittaken for pulmonary confumption; which is not owing primarily to the debility of the heart, but to its direct sympathy with the actions of the stomach.

M. M. Blifter. A plaster of Burgundy pitch on the abdomen. Opium a grain twice a day. Rhubarb fix grains every night. Bark. Steel. Spice. Bath-water. Siesta, or sleep after dinner. Uniform hours of meals. No liquor stronger than small beer, or wine and water. Gentle exercise on horseback in the open air uniformly perfifted in. See Cardialgia, I.

11. Cephalaa idiopathica. Head-achs, which are attended with inflammation, are termed phrenitis, described in Class II. 1. 2. 3. Those, which are not attended with inflammation, may be divided into fuch as affect the whole head, to which the word cephalæa is applied, and into fuch as affect one fide of the head only at a time, which is termed hemicrania. The former of these may be divided into cephalæa idiopathica, and cephalæa fympathetica; and the latter into hemicrania idiopathica, and hemicrania sympathetica. Besides these there exists a cephalæa fomniofa, a cephalæa fyphilitica, and a cephalæa hydropica.

The idiopathic head-ach frequently attends the cold paroxysm of intermittents; afflicts inebriates the day after intoxication; and many people who remain too long in the cold bath. In all which cases there is a general inaction of the whole system, and as these membranes about the head have been more exposed to the variations of heat and cold of the atmosphere, they are more liable to become affected fo far as to produce fensation, than other membranes; which are usually covered either with clothes, or with muscles, as mentioned in Sect. XXXIII. 2. 10.

The promptitude of the membranes about the scalp to sympathize with those of other parts of the system is so great, that this cephalæa without fever, or quickness of pulse, is more frequently a fecondary than a primary difease, and then belongs to Class IV. 2. 2. 7. The hemicrania, or partial head-ach, I believe to be almost always a disease from affociation; though it is not impossible, but a person may take cold on one side of the head only. As some people by fitting always on the same side of the fire in winter are liable to render one fide more tender than the other, and in consequence more subject to pains, which have been erroneously termed rheumatic.

Vol. II.

M. M. The method of cure confifts in rendering the habit more robust, by gentle constant exercise in the open air, stell diet, small beer at meals with one glass of wine, regular hours of rest and rising, and of meals. The clothing about the head should be warmer during sleep than in the day; because at that time people are more liable to take cold; that is, the membranous parts of it are more liable to become torpid; as explained in Sect. XVIII. 15. In respect to medicine, two drams of valerian root in powder three or four times a day are recommended by Fordyce. The bark. Steel in moderate quantities. An emetic. A blister. Opium, half a grain twice a day. Decayed teeth should be extracted, particularly such as either ache or are useless. Cold bath between 60 and 70 degrees of heat. Warm bath of 94 or 98 degrees every day for half an hour during a month. See Class IV. 2. 2. 7. and 8. and IV. 2. 4. 3.

A folution of arfenic, about the fixteenth part of a grain, is reported to have great effect in this difease. It should be taken thrice a day, if it produces no griping or sickness, for two or three weeks. A medicine of this kind is sold under the name of tasteless ague-drops; but a more certain method of ascertaining the quantity is delivered in the preceding Materia Medica, Art. IV. 2. 6. 8. Five grains of the powdered leaves of Atropa Belladonna are recommended in some foreign publication to be repeated once in two days, and are said to be successive.

ful in the dolor faciei, or hemicrania idiopathica.

Cephalea somniosa. Head-ach from sleep. This disease has not been described, I believe, by any writer, though it affects some invalids for years. After some hours of sleep the patients are afflicted with distressing dreams, and awake with pain of the head, which continues for some time after they awake; and so circumstanced surnishes the diagnostic symptom of this species of

cephalæa.

The paroxyfms or repetitions of many difeases are liable to commence in sleep, some from the increase of sensibility during sleep, as explained in Sect. XVIII. 5. and 15. of the first part of this work, as those of some epilepsies, of some asthmas, and of the gout. Other diseases are liable to return during sleep from the debility of the pulmonary circulation, or of pulmonary absorption, as in somnus interruptus, Class I. 2. 1. 3. and in incubus, or night-mare, Class III. 2. 1. 13. and in hæmoptoe venosa, Class I. 2. 1. 9. and probably in the humoral asthma, Class II. 1. 1. 8.

The cephalæa fomniosa I suspect to bear the same analogy to the hydrocephalus internus, as I believe the asthma humorale to bear to the anasarca pulmonum; and to consist in this circum-

stance,

stance, that during sleep in the cephalæa fomniosa a temporary congestion of sluid may occur in some part of the brain, as a permanent one occurs in the hydrocephalus internus; in the same manner as I believe in the asthma humorale a temporary congestion of sluid occurs in some part within the chest, and a

permanent one in the anafarca of the lungs.

M. M. The patient should sleep with his head raised high on many pillows, and wear drawers to prevent his slipping down in bed. 2. He should sleep on a hardish bed, or mattress, to prevent his sleeping too profoundly, or too long together. 3. Or he may be wakened, after having sleep a certain number of hours by an alarum clock. 4. Any carious teeth should be extracted, as the matter from putrid bones, swallowed with the saliva, weakens the system by its effect on the stomach. 5. Twenty drops of saturated tincture of digitalis may be taken twice or thrice a day for three or four weeks. 6. Half a grain of opium and six grains of rhubarb should be taken every night for many weeks or months. 7. Oxygen gas may be respired daily for a time, till its effect can be known.

12. Hemicrania idiopathica. This difease is described by Sauvage, under the name of trismus dolorisicus, or tic douloureux, in Class IV. ord. 1. gen. 2. spec. 14. of his elaborate work. But the word trismus is an improper name, as no fixed spasm like the locked jaw exists in this malady, nor any stridor dentium, or convulsion of the muscles of the face, or trick, attends these patients in the sew cases which I have witnessed, though this may possibly occur occasionally as the consequence of disagreeable sensation, or to relieve it. I suppose the word tic douloureux is a vulgar

French expression, like megrim in English.

The cause of this afflicting disease is yet unknown. As it does not appear to sympathize with a diseased tooth, like the hemicrania sympathetica, described in Class IV. 2. 2. 8. I suspect the cause to consist in a diseased state of the nerve itself, or of its covering or theca, and to resemble the sciatica frigida, mentioned below; or to resemble some of those pains, which are succeeded or relieved by epileptic convulsions, described in Class III. 1. 1. 8. and that it thus differs from the hemicrania sympathetica; as in this the cause of the disease, and the seat of the pain, exist in the same place.

One case, which occurred to me long ago, of this disease, was of an elderly gentleman, Mr. W. of Litchfield, who had long lost all his teeth; the pain began chiefly about the cheek-bone, and extended sometimes to the ala of the nose, and to other parts of the face on the same side; on examining the gums of the upper jaw, there was no suspicion of any stump of a decayed tooth

remaining

remaining in the alveolar processes; nor was there any reason to suspect any disease of the maxillary sinus. Whence this did not appear to be any kind of sympathetic hemicrania. He was af-

flicted with it for many years till his death.

The case of Mr. B. a gentleman between 20 and 30 years of age, whom I was lately concerned for, in this disease, is well worthy a minute description; I shall therefore copy a letter, which I wrote on his case to Mr. Cruikshank, and an answer I received some time after from his partner, Mr. Leigh Thomas, who I hope will publish the successful method of cure, with adapted prints.

To Mr. Cruiksbank.

Sir, Derby, Dec. 1798.

Mr. Bosworth, whose case I wish to remind you of, consulted you some time ago in London, and I believe that you then told him, that his head-ach was owing to a disease of the third branch of the fifth pair of nerves. He came under my care at Derby a few weeks ago, and complained of much pain about the left cheek-bone; I suspected the antrum maxillare might be diseased, and as the fecond of the dentes molares had then been lately extracted, I defired a perforation might be made into the antrum, which was done by Mr. Hadley, of this town, and kept open for two or three days without advantage. Afterwards, by friction about the head and neck with mercurial unguent, he was copiously falivated for a few days, and had another tooth extracted by his own defire, and had lastly an incision made by Mr. Hadley, fo as to divide the artery near the centre of the ear next the cheek, hoping to divide a branch of the affected nerve, but without fuccess; and internally, opiates in large quantity were given, when the pain was exceedingly violent, the bark also was used for a time in large quantity without effect.

On attending, as much as I could, to his fenfations when in pain, he feems to express the commencement of the periods of pain to exist about the part of the left cheek before the middle of the ear; and then draws his finger from thence to the fore part of the lower jaw sometimes, and to the ala of the nose on that side; and at other times he draws his singer from the same part of the cheek before the ear upwards to the orbit of the eye, and from thence downwards, a little way on the nose; and also he complains of pain under his tongue on the same side. The pain returns many times in an hour on some days, and continues many minutes, during which he seems to stretch and exert his arms, and appears to have a tendency to epileptic actions; and

his life is thus miserable to himself, and uncomfortable for his

friends to witness.

I write this to you to beg that you will acquaint Mr. Bofworth, whether you think you could divide by incision the discassed nerve; as he is willing to undergo such an operation, if you think it practicable, as I believe it to be the only means, which promises to cure him; and have therefore advised him again to apply to you; and if you think this can be done with effect, he designs to wait on you in London.

I am, fir, &c.

E. DARWIN.

The following answer of Mr. Leigh Thomas shews the disease to have existed in every branch of the affected nerve.

Sir, Leicester-square, May, 1799.

About the middle of December last, you did Mr. Cruikshank the favour to write him an account of Mr. Bosworth, a young gentleman, some time under your care at Derby, with a painful affection of the nerves of his face. The patient soon after came to town in a much worse state, than you described him to be at that time; as the pain was extremely acute and almost unremitting, opiates, which he had been in the habit of taking occasionally, afforded him now little or no relief, though taken to the quantity of six tea-spoonfuls of laudanum at a time. After paying every attention to the case, your suggestion of the necessity

of dividing the difeafed nerve appeared obvious.

As the pain was felt more acute in the left ala of the nose, and the upper lip of the same side, we were induced to divide the second branch of the fifth pair of nerves, as it passes out at the infraorbital foramen. He was instantly relieved in the nose and lip; but towards night the pain from the eye to the crown of the head became more acute than ever. Two days after, we were obliged to cut through the first branch passing out at the supra-orbital foramen; this afforded him the like relief with the first. On the same day the pain attacked, with great violence, the lower lip on the left side, and the chin; this circumstance induced the necessity of dividing the third branch passing out at the foramen mentale. During the whole period, from the first division of the nerves, he had frequent attacks of pain on the side of the tongue; these however disappeared on division of the last nerve.

Mr. Cruikshank performed the above operations, but being particularly engaged at this time with lectures and other business, he now gave up the case to my management. The patient was evidently bettered by each operation; still the pain was very

fevere,

fevere, passing from the ear under the zygoma towards the nose and mouth, and upwards round the orbit. This route proved pretty clearly, that the portio dura of the auditory nerve was also affected; at least the uppermost branch of the pes anserinus. Before I proceeded to divide this, I was willing to try the effect of arsenic internally, and he took it in sufficient quantity to excite nausea and vertigo, but without perceiving any good effect.

I could now trust only to the knife to alleviate his misery, as the pain round the orbit was become most violent; and therefore intercepted the nerve by an incision across the side of the nose, and also made some smaller incisions about the ala nasi. To divide the great branch lying below the zygomatic process, I sound it necessary to pass the scalpel through the masseter muscle, till it came in contact with the jaw-bone, and then to cut upwards; this relieved him as usual. Then the lower branch was affected, and also divided: then the middle branch running under the parotid gland. In cutting this, the gland was consequently divided into two equal parts, and healed tolerably well after a copious discharge of faliva for several days.

I hoped and expected, that this last operation would have terminated his sufferings and my dissipation; but the pain still affected the lower lip and side of the nose, and upon coughing, or swallowing, his misery was dreadful. This pain could only arise from branches from the second of the fifth pair passing into the cheek, and lying between the pterygoideus internus muscle, and the upper part of the lower jaw. The situation of this nerve rendered the operation hazardous, but after some attempts it was accomplished, and this day he set out for Leicestershire per-

fectly restored.

I am, fir, &c.
Leigh Thomas.

Since I wrote the above, I have feen an equally deplorable and instructive case, of hemicrania idiopathica, of an elderly person, described by Dr. Haighton, under the name of tic douloureux, with an equally successful cure, by dividing the diseased nerves.

Medical Records and Refearches. Cox, London.

Two cases of tic douloureux are related by a Dr. Watson, in the Recueil périodique de Médecine, Paris, 1798, tom. IV. which are said to have submitted to mercurial frictions and warm bathing. These pains were probably venereal symptoms, as the author suspects; but would persuade us again to try the use of mercury, though it sailed in the case above related, and especially as it sometimes succeeds in the hemicrania sympathetica, as mentioned in Class IV. 2. 2. 8. Five grains of the powdered leaf of belladonna

belladonna are said to have been successful. See Cephalæa idio.

pathica.

13. Odontalgia. Tooth-ach. The pain has been erroneously supposed, where there is no inflammation, to be owing to some acrid matter from a carious tooth stimulating the membrane of the alveolar process into violent action and consequent pain; but the effect seems to have been mistaken for the cause, and the decay of the tooth to have been occasioned by the torpor and consequent pain of the diseased membrane.

First, because the pain precedes the decay of the tooth in regard to time, and is liable to recur, frequently for years, without certainly being succeeded at last by a carious tooth, as I have

repeatedly observed.

Secondly, because any stimulant drug, as pyrethrum, or oil of cloves, applied to the tooth, or ether applied externally to the cheek, is so far from increasing the pain, as it would do if the pained membrane already acted too strongly, that it frequently

gives immediate relief like a charm.

And thirdly, because the torpor, or deficient action of the membrane, which includes the diseased tooth, occasions the motions of the membranes most connected with it, as those of the cheek and temples, to act with less than their natural energy; and hence a coldness of the cheek is perceived easily by the hand of the patient, comparing it with the other cheek; and the pain of hemicrania is often produced in the temple of the affected side.

This coldness of the cheek in common tooth-ach evinces, that the pain is not then caused by inflammation; because in all inflammations so much heat is produced in the secretions of new vessels and sluids, as to give heat to the parts in the vicinity. And hence, as soon as the gum swells and inflames along with the cheek, heat is produced, and the pain ceases, owing to the increased exertions of the torpid membrane, excited by the activity of the sensor of sensor of sensor of the painful torpid membrane. See

Odontitis, Class II. 1. 4. 7. and IV. 2. 2. 8.

M. M. If the painful tooth be found, venefection. Then a cathartic. Afterwards two grains of opium. Campher and opium, one grain of each held in the mouth; or a drop or two of oil of cloves put on the painful tooth. Ether. If the tooth has a small hole in it, this should be widened within by an instrument, and then stopped with leaf-gold, or leaf-lead; but the tooth should be extracted, if much decayed. It is probable that half a fraall drop of a strong solution of arsenic, put carefully into the hollow of a decayed aching tooth, would destroy the nerve without giving any additional pain; but this experiment requires

great

great caution lest any of the folution should touch the tongue or

gums

Much cold and much heat are equally injurious to the teeth, which are endued with a fine fenfation of this univerfal fluid. The best method of preserving them is by the daily use of a brush, which is not very hard, with warm water and fine charcoal dust. A lump of charcoal should be put a second time into the fire till it is red hot, as soon as it becomes cool the external ashes should be blown off, and it should be immediately reduced to fine powder in a mortar, and kept close stopped in a phial. It takes away the bad smell from decayed teeth, by washing the mouth with this powder diffused in water, immediately. The putrid smell of decaying stumps of teeth may be destroyed for a time by washing the mouth with a weak solution of alum in water. If the calcareous crust upon the teeth adheres very firmly, a fine powder of pumice-stone may be used occasionally, or a tooth-instrument.

Acid of fea-falt, much diluted, may be used; but this very rarely, and with the greatest caution, as in cleaning sea-shells. When the gums are spongy, they should be frequently pricked with a lancet. Should black spots in teeth be cut out? Does the enamel grow again when it has been perforated or abraded?

Otalgia. Ear-ach fometimes continues many days without apparent inflammation, and is then frequently removed by filling the ear with laudanum, or with ether; or even with warm oil, or warm water. See Class II. 1. 4. 8. This pain of the ear, like hemicrania, is frequently the consequence of affociation with a diseased tooth; in that case the ether should be applied to the cheek over the suspected tooth, or a grain of opium and as much camphor mixed together, and applied to the suspected tooth. In this case the otalgia belongs to the fourth class of diseases.

14. Pleurodyne chronica. Chronical pain of the fide. Pains of the membranous parts, which are not attended with fever, have acquired the general name of rheumatic; which should, nevertheless, be restricted to those pains which exist only when the parts are in motion, and which have been lest after inflammation of them; as described in Class I. 1. 3. 12. The pain of the fide here mentioned affects many ladies, and may possibly have been owing to the pressure of tight stays, which has weakened the action of the vessels composing some membranous part, as, like the cold head-ach, it is attended with present debility; in one patient, a boy about ten years old, it was attended with daily convulsions, and was supposed to have originated from worms. The discase-is very frequent, and generally withstands the use of blisters on the part; but in some cases I have known

it removed by electric shocks repeated every day for a fortnight

through the affected fide.

Pains of the fide may be fometimes occasioned by the adhefion of the lungs to the pleura, after an inflammation of them; or to the adhesion of some abdominal viscera to their cavity, or to each other; which also are more liable to affect ladies from the unnatural and ungraceful pressure of tight stays, or by sitting or lying too long in one posture. But in these cases the pain should be more of the smarting, than of the duli kind.

M. M. Ether. A blifter. A platter of Burgundy pitch. An iffue or feton on the part. Electric shocks. Friction on the part with oil and camphor. Loose dress. Frequent change of posture both in the day and night. Internally, opium, valu-

rian, bark.

15. Sciatica frigida. Cold sciatica. The pain along the course of the sciatic nerve, from the hip quite down to the top of the foot, when it is not attended with sever, is improperly termed either rheumatism or gout; as it occurs without imhummation, is attended with pain when the limb is at rest; and as the pain attends the course of the nerve, and not the course of the muscles, or of the sascia which contains them. The theory of Cotunnius, who believed it to be a dropsy of the sheath of the nerve, which was compressed by the accumulated shuid, has not been confirmed by diffection. The disease seems to consist of a torpor of this sheath of the nerve, and the pain seems to be in consequence of this torpor. See Class II. 1. 2. 17.

M. M. Venefection. A cathartic. And then one grain of calomel and one of opium every night for ten successive nights. And a blitter, at the same time, a little above the knee-joint on the outside of the thigh, where the sciatic nerve is not so deep scated. Warm bath. Cold bath. Cover the limb with oned

filk, or with a plaster-bandage of emplastrum de minio.

16. Lumbago frigida. Cold lumbago. When no fever or inflammation attends this pain of the loins, and the pain exists without motion, it belongs to this genus of diseases, and refembles the pain of the loins in the cold sit of ague. As these membranes are extensive, and more easily fall into quiescence, either by sympathy, or when they are primarily affected, this disease becomes very afflicting, and of great pertinacity. See Class II.

1. 2. 17.

M. M. Venefection. A cathartic. Issues on the lains. Adhesive plaster on the lains. Blitter on the os facrum. Warm bath. Cold bath. Remove to a warmer climate in the winter. Loofe dress about the waist. Friction daily with oil and cam-

phor.

17. Hyseralgia frigida. Cold pain of the uterus preceding or accompanying menstruation. It is attended with cold extremities, want of appetite, and other marks of general debility.

M. M. A clyster of half a pint of gruel, and 30 drops of laudanum; or a grain of opium and six grains of rhubarb every night. To sit over warm water, or go into a warm bath.

18. ProEtalgia frigida. Cold pain at the bottom of the rectum previous to the tumor of the piles, which fometimes extends by fympathy to the loins; it feems to be fimilar to the pain at the beginning of menstruation, and is owing to the torpor or inirritability of the extremity of the alimentary canal, or to the obstruction of the blood in its passage through the liver, when that viscus is affected, and its consequent delay in the veins of the rectum, occasioning tumours of them, and dull sensations of pain.

M. M. Calomel. A cathartic. Spice. Clyster, with 30 drops of laudanum. Sitting over warm water. If chalybeates after evacuation? See Class I. 2. 3. 23. and I. 2. 1. 6.

19. Vefice fellea inirritabilitas. The inirritability of the gall-bladder probably occasions one kind of ieterus, or jaundice; which is owing to whatever obstructs the passage of bide into the duodenum. The jaundice of aged people, and which attends some severs, is believed to be most frequently caused by an irritative passy of the gall-bladder; on which account the bile is not pressed from the cyst by its contraction, as in a paralysis of the urinary bladder.

A thickening of the coats of the common bile-duct by inflammation or increased action of their vessels so as to prevent the passage of the bile into the intestine, in the same manner as the membrane, which lines the nostrils, becomes thickened in catarrh so as to prevent the passage of air through them, is probably another frequent cause of jaundice, especially of children; and generally ceases in about a fortnight, like a common catarrh, without the aid of medicine; which has given rise to the character, which charms have obtained in some countries for curing the jaundice of young people.

The spissitude of the bile is another cause of jaundice, as mentioned in Class I. 1. 3. 8. This also in children is a disease of little danger, as the gall-ducts are distensible, and will the easier admit of the exclusion of gall-stones; but becomes a more serious disease in proportion to the age of the patient, and his habits

of life in respect to spirituous potation.

A fourth cause of jaundice is the compression of the bile-duct by the enlargement of an inflamed or scirrhous liver; this attends those who have drunk much spirituous liquor, and is generally

fucceeded by dropfy and death.

M. M. Repeated emetics. Mild cathartics. Warm bath. Electricity. Bitters. Then steel, which, when the pain and inflammation are removed by evacuations, acts like a charm in removing the remainder of the inflammation, and by promoting the absorption of the new vessels or fluids; like the application of any acrid eye-water at the end of ophthalmia; and thus the thickened coats of the bile-duct become reduced, or the enlargement of the liver leffened, and a free paffage is again opened for the bile into the intestine. Ether with yolk of egg is recommended, as having a tendency to diffolve inspiffated bile. a decoction of madder is recommended for the same purpose; because the bile of animals, whose food was mixed with madder, was found always in a dilute state. Aerated alkaline water, or Seltzer water. Raw cabbage, and other acrid vegetables, as water-croffes, mustard. Horses are said to be subject to inspiffated bile, with yellow eyes, in the winter feafon, and to get well as foon as they feed on the spring grass.

The largest bile-stone I have seen was from a lady, who had parted with it some years before, and who had abstained above ten years from all kinds of vegetable diet to prevent, as the supposed, a colic of her stomach, which was probably a pain of the biliary duct; on resuming the use of some vegetable diet, she recovered a better state of health, and formed no new bilious

concretions.

A strong aerated alkaline water is fold by J. Schweppe, No.

8, King-street, Holborn. See Class I. 1. 3. 10.

20. Pelvis renalis inirritabilitas. Inirritability of the pelvis of the kidney. When the nucleus of a stone, whether it be infpissated mucus, or other matter, is formed in the extremity of any of the tubuli uriniferi, and being detached from thence falls into the pelvis of the kidney, it is liable to lodge there from the want of due irritability of the membrane; and in that situation increases by new appositions of indurated animal matter, in the same manner as the stone of the bladder. This is the general cause of hæmorrhage from the kidney; and of obtuse pain in it on exercise; or of acute pain, when the stone advances into the ureter. See Class I. 1. 3. 9.

ORDO II.

Decreased Irritation.

GENUS V.

Decreased Action of the Organs of Sense.

SPECIES.

of perception. When the motions of the fibrous extremities of the nerves of fense are too weak, to excite sensation with sufficient quickness and vigour. The irritative ideas are nevertheless performed, though perhaps in a feeble manner, as such people do not run against a post, or walk into a well. There are three other kinds of folly; that from descient sensation, from descient volition, and from descient association, as will be mentioned in their places. In delirium, reverie, and sleep, the pow-

er of perception is abolished from other causes.

2. Vifus imminatus. Diminished vision. In our approach to old age our vision becomes imperfect, not only from the form of the cornea, which becomes less convex, and from its decreased transparency mentioned in Class I. 1. 3. 14; but also from the decreased irritability of the optic nerve. Thus, in the inirritative or nervous sever, the pupil of the eye becomes dilated; which in this, as well as in the dropsy of the brain, is generally a fatal symptom. A part of the cornea as well as a part of the albuginea in these fevers is frequently seen during sleep; which is owing to the inirritability of the retina to light, or to the general paresis of muscular action, and in consequence to the less contraction of the sphincter of the eye, if it may be so called, at that time

In some eyes there is an inaptitude to adapt themselves to the perception of objects at disserent distances, which I suppose may be owing to the inirritability of those muscular sibres, which constitute the ciliary process, so well described and explained by Dr. Portersield, and in the Scots Medical Eslays, and so elegantly seen in a dissected eye. It was formerly believed, and has indeed lately been again pretended, that the socus of the crystalline humour was adapted to objects at different distances by a change of the shape of the whole eve by the action of the external muscles, which are inferted into the tunica albuginea, and give motion to it in every direction: but in answer to this may be

observed, that if the common actions of the muscles affected the focus of the eye, every motion of the eye-ball, when we attend to objects at any distance, must disturb our vision. At the same time though it is possible, that a violent action of all the muscles together, so as to counter-balance each other, and keep the eye motionless, as when we look painfully at a very distant object, may in some degree affect the form of it; yet that the contraction of the ciliary process perpetually adapts the socus of the crystalline lens to the distance of the retina is not to be disputed.

There have been instances of some, who could not distinguish certain colours; and yet whose eyes, in other respects, were not imperfect. Philos. Transact. Which seems to have been owing to the want of irritability, or the inaptitude to action, of some classes of sibres which compose the retina. Other permanent defects depend on the diseased state of the external organ.

Chais I. 1. 3. 14. I. 2. 2. 13. IV. 2. 1. 11.

3. Musica volitantes. Dark spots appearing before the eyes, and changing their apparent place with the motions of the eyes, are owing to a temporary defect of irritability of those parts of the retina, which have been lately exposed to more luminous objects than the other parts of it, as explained in Sect. XL. 2. Hence dark spots are seen on the bed-clothes by patients, when the optic nerve is become less irritable, as in severs with great debility; and the patients are perpetually trying to pick them off with their singers to discover what they are; for these parts of the retina of weak people are sooner exhausted by the stimulus of bright colours, and are longer in regaining their irritability.

Other kinds of ocular spectra, as the coloured ones, are also more liable to remain in the eyes of people debilitated by severs, and to produce various hallucinations of fight. For after the contraction of a muscle, the fibres of it continue in the last situation, till some antagonist muscles are exerted to retract them; whence, when any one is much exhausted by exercise, or by want of sleep, or in severs, it is easier to let the fibres of the retina remain in their last situation, after having been stimulated into contraction, than to exert any antagonist fibres to replace them.

As the optic nerves at their entrance into the eyes are each of them as thick as a crow-quill, it appears that a great quantity of fenforial power is expended during the day in the perpetual activity of our fenfe of vision, besides that used in the motions of the eye-balls and eye-lids; as much I suppose as is expended in the motions of our arms, which are supplied with nerves of about the same diameters. From hence we may conclude, that the light should be kept from patients in severs with debility, to prevent the unnecessary exhaustion of the sensorial power.

And that on the same account their rooms should be kept silent as well as dark; that they should be at rest in a horizontal posture; and be cooled by a blast of cool air, or by washing them with cold water, whenever their skins are warmer than natural.

4. Strabifmus. Squinting is generally owing to one eye being lefs perfect than the other; on which account the patient endeavours to hide the worst eye in the shadow of the nose, that his vision by the other may not be confused. Calves which have an hydatide with insects inclosed in it in the frontal sinus on one side, turn towards the affected side; because the vision on that side, by the pressure of the hydatide, becomes less perfect; and the disease being recent, the animal turns round, expeding to get a more distinct view of objects.

In the hydrocephalus internus, where both eyes are not become infenfible, the patient fquints with only one eye, and views objects with the other, as in common strabismus. In this case it may be known on which side the disease exists, and that it does not exist on both sides of the brain; in such circumstances, as the patients I believe never recover as they are now treated, might it not be adviseable to perforate the cranium over the ventricule of the affected side? which might at least give room and

ftimulus to the affected part of the brain?

M. M. If the fquinting has not been confirmed by long habit, and one eye be not much worse than the other, a piece of gauze stretched on a circle of whale-bone, to cover the best eye in such a manner as to reduce the distinctness of vision of this eye to a similar degree of imperfection with the other, should be worn some hours every day. Or the better eye should be totally darkened by a tin cup covered with black silk for some hours daily, by which means the better eye will be gradually weakened by the want of use, and the worse eye will be gradually strengthened by using it. Covering an inslamed eye in children for weeks together, is very liable to produce squinting, for the same reason.

5. Amaurosis. Gutta serena. Is a blindness from the inirritability of the optic nerve. It is generally esteemed a palfy of the nerve, but should rather be deemed the death of it, as paralysis has generally been applied to a deprivation only of voluntary power. This is a disease of dark eyes only, as the cataract is a disease of light eyes only. At the commencement of this disease, very minute electric shocks should be repeatedly passed through the eyes; such as may be produced by putting one edge of a piece of silver the size of a half crown piece beneath the tongue, and one edge of a piece of zinc of a similar size between the upper lip and the gum,

and then repeatedly bringing their exterior edges into contact, by which means very small electric sparks become visible in the

Mrs. T-had for some weeks complained of imperfect fight. For the last fortnight she could not in less than a minute fpell out a fingle word in a large print. Her eyes black, and the pupils large. Very flight electric shocks, not sparks, were passed through the forepart of her forehead twice a day, and the zinc and filver pencils as mentioned below were used many times a She took valerian and columbo internally, and regained her fight very perfectly in about three weeks.

I used in the above case a more convenient and efficacious method of galvanism by employing two rods, one of them of zinc about the fize of a writing pencil, and the other a filver pencilcase about the same size; and by putting the end of the zinc rod in contact with the external corner of one eye, and the end of the filver pencil-case in contact with the external corner of the other eve, and then repeatedly making the other ends touch each other; sparks will be visible in the eyes both at the time of contact and at the time of separation of the two rods. This experiment was published by Volta since the former one by Galvani. See Sect. XIV. 5. of Vol. I.

A foreign physician, professor Arnemann, has lately recommended the production of vertigo in gutta ferena, as he fays, to accumulate more blood in the head. If this should be really found of advantage the patient might lie on a large mill-stone, which might be fuffered to turn flowly, but a very great velocity of the whirling stone might occasion sleep, apoplexy, and death.

See Supl. I. 15. 7.

M. M. Minute electric shocks. A grain of opium, and a quarter of a grain of corrolive fublimate of mercury, twice a day for four or fix weeks. Blifter on the crown of the head. rhines, fo as to induce violent fneezing twice a day for a week.

6. Auditus imminutus. Diminished hearing. Deafness is a frequent fymptom in those inflammatory or sensitive fevers with debility, which are generally called putrid; it attends the general Aupor in those fevers, and is rather esteemed a salutary sign, as during this stupor there is less expenditure of sensorial power.

In fevers of debility without inflammation, called nervous fevers, I suspect deafness to be a bad symptom, arising, like the dilated pupil, from a partial paralysis of the nerve of sense.

Class IV. 2. 1. 15.

Nervous fevers are supposed by Dr. Cilchrist to originate from a congestion of serum or water in some part of the brain, as many of the symptoms are so similar to those of hydrocephalus inter-

nus, in which a fluid is accumulated in the ventricles of the brain; on this idea the inactivity of the optic or auditory nerves in these fevers may arise from the compression of the essured sluid; while the torpor attending putrid fever may depend on the meninges of the brain being thickened by inflammation, and thus compressing it; now the new vessels, or the blood, which thickens inflamed parts, is more frequently re-abforbed, than the effused fluid from a cavity; and hence the stupor in one case is less dangerous than in the other.

In inflammatory or fensitive fevers with debility, deafnels may fometimes arise from a greater secretion and absorption of the ear-wax, which is very fimilar to the bile, and is liable to fill the meatus auditorius, when it is too viscid, as bile obstructs the gall-

ducts.

M. M. In deafness without fever, Dr. Darwin applied a cupping-glass on the ear with good effect, as described in Phil. Trans. Vol. LXIV. p. 348. Oil, ether, laudanum, dropped into

the ears. Errhines. Electricity.

If ether when dropped into the ears be not very pure, it is liable to give pain; it has otherwise the property both of disfolving the ear-wax, and of stimulating torpid parts into their accustomed activity, as is known from its relieving pains from inactivity of the pained part, as tooth-ach and head-ach. If unrectified ether be distilled from the oxyde of manganese, the oxygen disengaged from the manganefe is afferted to convert the fulphurous into sulphuric acid, which is then not disposed to rise in distillation. Journal de Physique, April, 1798. And that this is the great fecret of procuring pure ether, and it will then give no pain

on being dropped into the ear. See Art. II. 2. 3.

Deafness is believed sometimes to arise from obstruction of the Eustachian tubes, which communicate from the fauces to the internal ear behind the tympanum; if this obstruction be slight, as by inspissated mucus, it has been proposed to inject the Eustachian tubes; and it is faid, that if the deaf perion frequently has recourse to the simple action of shutting his mouth and of closing his nostrils by pinching them together with his finger and thumb, and then forcibly endeavours to press the breath through his nofe, that air will pass into the internal ear through the Euflachian tubes, condensing that air which exists behind the tympanum; which the patient will himself be sensible of, by a senfation of found in his ears. And that this has relieved many.

Where an eruption occurs in the ear, followed by a dry scale or feab at the bottom of the meatus auditorius, a folution of corrofive fublimate of mercury, hydrargyrus muriatus, about one grain to an ounce of water, dropped into the ear, frequently has

been used with advantage by Dr. Darwin of Shrewsbury. See

Clais IV. 2. 1. 15.

7. Olfactus imminutus. Inactivity of the fense of smell. From our habits of trusting to the art of cookery, and not examining our food by the smell as other animals do, our sense of smell is less perfect than theirs. See Sect. XVI. 5. Class IV. 2. 1. 16.

M. M. Mild errhines.

8. Gustus imminutus. Want of taste is very common in fevers, owing frequently to the dryness or scurf of the tongue, or external organ of that sense, rather than to any injury of the nerves of taste. See Class I. 1. 3. 1. IV. 2. 1. 16.

M. M. Warm fubacid liquids taken frequently.

9. Tactus imminutus. Numbness is frequently complained of in fevers, and in epilepsy, and the touch is sometimes impaired by the dryness of the cuticle of the fingers. See Class IV. 2.1. 16.

When the fense of touch is impaired by the compression of the nerve, as in fitting long with one thigh croffed over the other, the limb appears larger, when we touch it with our hands, which is to be afcribed to the indiffinctness of the fensation of touch, and may be explained in the fame manner as the apparent largeness of objects seen through a mist. In this last case the minute parts of an object, as suppose of a distant boy, are feen lefs diffinctly, and therefore we infantly conceive them to be further from the eye, and in confequence that the whole fubtends a larger angle, and thus we believe the boy to be a man. So when any one's fingers are pressed on a benumbed limb, the fenfation produced is lefs than it should be, judging from visible circumstances; we therefore conceive, that something intervened between the object and the fenfe, for it is felt as if a blanket was put between them; and that not being visibly the case. we judge that the limb is fwelled.

The fenfe of touch is also liable to be deceived from the acquired habits of one part of it acting in the vicinity of another part of it. Thus if the middle finger be crossed over either of the fingers next to it, and a nut be felt by the two ends of the fingers fo crossed at the same time, the nut appears as if it was two nuts. And lastly, the sense of touch is liable to be deceived by preconceived ideas; which we believe to be excited by external objects, even when we are awake. It has happened to me more than once, and I suppose to most others, to have put my hands into an empty bason, standing in an obscure corner of a room, to wath them, which I believed to contain cold water, and have instantly perceived a fensation of warmth, contrary to that which I expected to have felt.

Vol. II.

In some paralytic affections, and in cold fits of ague, the senfation of touch has been much impaired, and yet that of heat has remained. See Sect. XIV. 6.

M. M. Friction alone, or with camphorated oil, warm bath. Ether. Volatile alkali and water. Internally, spice, falt. Incitantia. Secernentia.

To. Stupor. The stupor, which occurs in fevers with debility, is generally esteemed a favourable symptom; which may arise from the less expenditure of sensorial power already existing in the brain and nerves, as mentioned in species 6 of this genus. But if we suppose, that there is a continued production of sensorial power, or an accumulation of it in the torpid parts of the system, which is not improbable, because such a production of it continues during sleep, to which stupor is much allied, there is still further reason for believing it to be a favourable symptom in inirritable severs; and that much injury it often done by blisters and other powerful stimuli to remove the stupor. See Sect. XII. 7. 8: and XXXIII. 1. 4.

Dr. Blane, in his Croonian Lecture on muscular motion, for 1788, among many other ingenious observations and deductions, relates a curious experiment on salmon, and other fish, and which

he repeated upon eels with fimilar event.

"If a fish, immediately upon being taken out of the water, is ftunned by a violent blow on the head, or by having the head crushed, the irritability and sweetness of the museless will be preferved much longer, than if it had been allowed to die with the organs of sense entire. This is so well known to sishermen, that they put it in practice, in order to make them longer susceptible of the operation called crimping. A salmon is one of the fish least tenacious of life, insomuch, that it will lose all signs of life in less than half an hour after it is taken out of the water, if suffered to die without any farther injury; but if, immediately after being caught, it receives a violent blow on the head, the muscles will shew visible irritability for more than twelve hours afterwards.

Dr. Blane afterwards well remarks, that, " in those diforders in which the exercise of the senses is in a great measure destroyed, or suspended, as in the hydrocephalus, and apoplectic palfy, it happens, not uncommonly, that the appetite and degestion are better than in health."

ORDO III.

Retrograde Irritative Motions.

GENUS I.

Of the Alimentary Canal.

THE retrograde motions of our system originate either from defect of stimulus, or from defect of irritability. Thus sickness is often induced by hunger, which is a want of stimulus; and from ipecacuanha, in which last case it would feem, that the sickness was induced after the violence of the stimulus was abated, and the consequent torpor had succeeded. Hence, spice, opium, or food, relieves sickness.

The globus hystericus, falivation, diabetes, and other inverfions of motion attending hysteric paroxysms, seem to depend on the want of irritability of those parts of the body, because they are attended with cold extremities, and general debility, and are relieved by wine, opium, steel, and sleih diet; that is, by

any additional stimulus.

When the longitudinal muscles are fatigued by long action, or are habitually weaker than natural, the antagonist muscles replace the limb by stretching it in a contrary direction; and as these muscles have had their actions associated in synchronous tribes, their actions ceafe together. But as the hollow muscles propel the fluids, which they contain, by motions affociated in trains; when one ring is fatigued from its too great debility, and brought into retrograde action; the next ring, and the next, from its affociation in train falls into retrograde action. Which continue fo long as they are excited to act, like the tremors of the hands of infirm people, fo long as they endeavour to act. Now as these hollow muscles are perpetually stimulated, these retrograde actions do not cease as the tremors of the longitudinal muscles, which are generally excited only by volition. Whence the retrograde motions of hollow muscles depend on two circumstances, in which they differ from the longitudinal muscles, namely, their motions being associated in trains, and their being subject to perpetual stimulus. For further elucidation of the cause of this curious source of diseases, see Sect. XXIX. 11. 5.

The fluids difgorged by the retrograde motions of the various vafcular muscles may be distinguished, 1. From those, which are produced by secretion, by their not being attended by increase

of heat, which always accompanies increased secretion. 2. They may be distinguished from those sluids, which are the consequence of deficient absorption, by their not possessing the saline acrimony, which those sluids possess; which inslames the skin or other membranes on which they fall; and which have a saline taste to the tongue. 3. They may be distinguished from those sluids, which are the consequence both of increased secretion and absorption, as these are attended with increase of warmth, and are inspillated by the abstraction of their ageous parts. 4. Where chyle, or milk, is found in the seces or unine, or when other sluids, as matter, are translated from one part of the system to another, they have been the product of retrograde action of lymphatic or other canals. As explained in Sect. XXIX. 8.

SPECIES.

r. Ruminatio. In the rumination of horned cattle the retrograde motions of the cesophagus are visible to the eye, as they bring up the softened grass from their first stomach. The vegetable aliment in the first stomach of cattle, which have filled themselves too full of young clover, is liable to run into fermentation, and distend the stomach, so as to preclude its exit, and frequently to destroy the animal. To discharge this air the farmers frequently make an opening into the stomach of the animal with success. I was informed, I believe by the late Dr. Whytt of Edinburgh, that of twenty cows in this situation two had died, and that he directed a pint of gin or whisky, mixed with an equal quantity of water, to be given to the other eighteen; all of which eructed immense quantities of air, and recovered.

There are histories of ruminating men, and who have taken pleasure in the act of chewing their food a second time. Philos. Transact.

2. Ructus. Eructation. An inverted motion of the stomach excluding through its upper valve an elastic vapour, generated by the fermentation of the aliment; which proceeds so hastily, that the digestive power does not subdue it. This is sometimes acquired by habit, so that some people can eruct when they please, and as long as they please; and there is gas enough generated to supply them for this purpose; for by Dr. Hales's experiments, an apple, and many other kinds of aliment, give up above six hundred times their own bulk of an elastic gas in fermentation. When people voluntarily eject the fixable air from their stomachs, the fermentation of the aliment proceeds the faster; for stopping the vessels, which contain new wines, retards their fermentation.

mentation, and opening them again accelerates it; hence where the digeftion is impaired, and the Homach fomewhat diftended with air, it is better to restrain than to encourage eructations, except the quantity makes it necessary. When wine is confined in bottles, the fermentation still proceeds slowly even for years, till all the sugar is converted into spirit; but in the process of digestion, the saccharine part is absorbed in the form of chyle by the bibulous mouths of the numerous lacteals, before it has time to run into the vinous fermentation.

3. Apeplia. Indigestion. Water-qualm. A few mouthfuls of the aliment are rejected at a time for some hours after meals. When the aliment has had time to ferment, and become acid, it produces cardialgia, or heart-burn. This difease is perhaps generally left after a flight inflammation of the stomach, called a furfeit, occasioned by drinking cold liquors, or eating cold vegetables, when heated with exercise. This inflammation of the fromach is frequently, I believe, at its commencement removed by a critical eruption on the face, which differs in its appearance as well as in its cause from the gutta rosea of drunkards, as the tkin round the bate of each eruption is less inflamed. See Class II. 1. 4. 6. This difease differs from Cardialgia, Class I. 2. 4. 5. in its being not uniformly attended with pain of the cardia ventriculi, and from its retrograde motions of a part of the stomach about the upper orifice of it. In the same manner as hysteria differs from hypochondrialis; the one confifting in the weakness and indigestion of the same portions of the alimentary canal, and the other in the inverted motions of some parts of it. This apepfia or water-qualm continues many years, even to old age; Mr. G of Litchfield fuffered under this disease from his infancy; and, as he grew old, found relief only from repeated dofes of opium.

M. M. A blister, rhubarb, a grain of opium twice a day.

Soap, iron-powder. Tin-powder.

4. Vomitus. An inverted order of the motions of the stomach and cesophagus with their absorbent vessels, by which their contents are evacuated. In the act of vomiting less sensorial power is employed than in the usual peristaltic motion of the stomach, as explained in Sect. XXXV. 1. 3. Whence after the operation of an emetic the digestion becomes stronger by an accumulation of sensorial power during its decreased action. This decreased action of the stomach may be either induced by want of stimulus, as in the sickness which attends hunger; or it may be induced by temporary want of irritability, as in cold sits of sever; or from habitual want of irritability, as the vomiting

of enfeebled drunkards. Or lastly, by having been previously too violently stimulated by an emetic drug, as by ipecacuanha.

M. M. A blifter. An emetic. Opium. Warmth of a bed, covering the face for a while with the bed-clothes. Crude mer-

cury. A poultice with opium or theriaca externally.

5. Cholera. When not only the ftomach, as in the last article, but also the duodenum, and ileum, as low as the valve of the colon, have their motions inverted; and great quantities of bile are thus poured into the stomach; while at the same time some branches of the lacteals become retrograde, and disgorge their contents into the upper part of the alimentary canal; and other branches of them disgorge their contents into the lower parts of it beneath the valve of the colon; a vomiting and purging commence together, which is called cholera, as it is supposed to have its origin from increased secretion of bile; but I suppose more frequently arises from putrid food, or poisonous drugs, as in the case narrated in Sect. XXV. 13. where other circumstances of this disease are explained. See Class II. 1. 2. 11.

The cramps of the legs, which are liable to attend cholera,

are explained in Class III. 1. 1. 15.

6. Ileus. Confifts in the inverted motions of the whole intestinal canal, from the mouth to the anus; and of the lacteals and absorbents which arise from it. In this pitiable disease, through the valve of the colon, through the pylorus, the cardia, and the pharynx, are ejected, first, the contents of the stomach and intestines, with the excrement and even clysters themselves; then the sluid from the lacteals, which is now poured into the intestines by their retrograde motions, is thrown up by the mouth; and, lastly, every fluid, which is absorbed by the other lymphatic branches, from the cellular membrane, the skin, the bladder, and all other cavities of the body; and which is then poured into the stomach or intestines by the retrograde motions of the lacteals; all which supply that amazing quantity of sluid, which is in this disease continually ejected by vomiting. See Sect. XXV. 15. for a further explanation of this disease.

M. M. Copious venetection. Twenty grains of calomel in fmall pills, or one grain of aloe every hour till stools are procured. Blisters. Warm bath. Crude mercury. Clyster of icewater. Smear the skin all over with grease, as mentioned in

Sect. XXV. 15.

As this malady is occasioned sometimes by an introsusception of a part of the intestine into another part of it, especially in children, could holding them up by their heels for a second or two of time be of service after venesection? Or the exhibition of crude quicksilver two ounces every half hour, till a pound is

taken, be particularly ferviceable in this circumstance? Or could half a pound, or a pound, of crude mercury be injected as a clyster, the patient being elevated by the knees and thighs so as to have his head and shoulders much lower than his bottom, or even for a short time held up by the heels? Could this also

be of advantage in strangulated hernia?

Where there exists an introsusception of the intestine, or in obstinate costiveness, perhaps a forcing pump, such as gardeners employ to water their trees, might be used with advantage, by driving water forcibly up the rectum, as is mentioned by Mr. Adair; and was used by Dettaen in experiments on dogs, who found the valve of the colon did not prevent warm water being pushed along the whole course of the alimentary canal by a forcing syringe. This is well worthy trial, as well as the quick-silver introduced by the anus in inflammations of the intestines,

where no passage downwards can be procured.

Where an introfusception of the intestine exists, as is believed frequently to occur in those inflammations of the bowels of children, which are not owing to some indigestible material, as to plum stones or cherry stones, it is probable that a quantity of air alone, or of the smoke of tobacco, might be injected so forcibly as to dilate, and in consequence to pass the valve of the colon; and might push into its place the strangulated suplicature of the intestine. Air might be thus injected from a large brown bladder by means of a clyster-pipe covered with soft leather moistened with oil or mucilage, or by means of bellows, or the common apparatus for injecting the smoke of tobacco, or by a syringe used for condensing air in philosophical experiments. I have seen school-boys blow air through a grass-steminto the bowels of frogs, so as to prevent their diving, without injuring them.

Where the difease is owing to strangulated hernia, the part should be sprinkled with cold water, or iced water, or falt and water recently mixed, or moistened with ether. In cases of strangulated hernia, could a cupuncture, or puncture with a capillary trocar, be used with safety and advantage to give exit to air contained in the strangulated bowel? Or to stimulate it into action? It is not uncommon for bashful men to conceal their being afflicted with a small hernia, which is the cause of their death; this circumstance should therefore always be inquired into. Is the seat or cause of the ileus always below the valve of the colon, and that of the cholera above it? See Class

11. 1. 2. 11.

7. Globus hystericus. Hysteric suffocation is the perception of a globe rolling round in the abdomen, and ascending to the stomach and throat, and there inducing strangulation. It con-

inits

fifts of an ineffectual invertion of the motions of the cefophagus, and other parts of the alimentary canal; nothing being rejected from the stomach.

M. M. Tincture of castor, tinct. of opium, of each 15 drops.

See Hysteria, Class I. 3. 1. 9.

8. Vomendi conamen inane. An ineffectual effort to vomit. It frequently occurs, when the stomach is empty, and in some cases continues many hours; but as the lymphatics of the stomach are not inverted at the same time, there is no supply of materials to be ejected; it is sometimes a symptom of hysteria, but more frequently attends irregular epilepsies or reveries; which however may be distinguished by their violence of exertion, for the exertions of hysteric motions are feeble, as they are caused by debility; but those of epilepsies, as they are used to relieve pain, are of the most violent kind; insomuch that those who have once seen these ineffectual efforts to vomit in some epilepsies, can never again mistake them for symptoms of hysteria. See a case in Sect. XIX. 2.

M. M. Blister. Opium. Crude mercury.

9. Borborigmus. A gurgling of the bowels proceeds from a partial invertion of the periltaltic motions of them, by which the gas is brought into a fuperior part of the bowel, and bubbles through the descending sluid, like air rushing into a bottle as the water is poured out of it. This is fometimes a diffreshing fymptom of the debility of the bowels joined with a partial inversion of their motions. I attended a young lady about fixteen, who was in other respects feeble, whose bowels almost incessantly made a gurgling noise so loud as to be heard at a considerable distance, and to attract the notice of all who were near her. As this noise never ceased a minute together for many hours in a day, it could not be produced by the uniform defcent of water, and afcent of air through it, but there must have been alternately a retrograde movement of a part of the bowel, which must again have pushed up the water above the air; or which might raise a part of the bowel, in which the fluid was lodged, alternately above and below another portion of it; which might readily happen in some of the curvatures of the smaller intestines, the air in which might be moved backward and forward like the airbubble in a glass-level.

M. M. Effential oil. Ten corns of black pepper fwallowed whole after dinner, that its effect might be flower and more permanent; a fmall pipe occasionally introduced into the rectum to facilitate the cscape of the air. Crude mercury. See Class I.

2. 4. 8.

10. Hyleria. The three last articles, together with the lymphatic

phatic diabetes, are the most common symptoms of the hysteric disease; to which sometimes is added the lymphatic salivation, and fits of syncope, or convulsion, with palpitation of the heart (which probably consists of retrograde motions of it), and a great fear of dying. Which last circumstance distinguishes these convulsions from the epileptic ones with greater certainty than any other single symptom. The pale copious urine, cold skin, palpitation, and trembling, are the symptoms excited by great fear. Hence in hysteric diseases, when these symptoms occur, the fear, which has been usually associated with them, recurs at the same time, as in hypochondriasis, Class I. 2. 4. 10. See Sect. XVI. 8. 1.

The convultions which fometimes attend the hyfteric difease, are exertions to relieve pain, either of some torpid, or of some retrograde organ; and in this respect they resemble epileptic convulsions, except that they are seldom to violent as entirely to produce insensibility to external stimuli; for these weaker pains cease before the total exhaustion of sensorial power is produced, and the patient sinks into impersect syncope; whereas the true epilepsy generally terminates in temporary apoplexy, with perfect insensibility to external objects. These convulsions are less to be dreaded than the epileptic ones, as they do not originate from so permanent a cause.

The great discharge of pale urine in this disease is owing to the inverted motions of the lymphatics, which arise about the neck of the bladder, as described in Sect. XXIX. 4.5. And the lymphatic salivation arises from the inverted motions of the

falivary lymphatics.

Hysteria is distinguished from hypochondriasis, as in the latter there are no retrograde motions of the alimentary canal, but simply a debility or inirritability of it, with distention and statulency. It is distinguished from apepsia and cardialgia by there being nothing ejected from the stomach by the retrograde motions of it,

or of the cefophagus.

M. M. Opium. Camphor. Afafectida. Caftor, with finapifms externally; to which must be added a clyster of cold water, or iced water; which, according to Mons. Pomme, relieves these hysteric symptoms inftantaneously like a charm; which it may effect by checking the inverted motions of the intestinal canal by the torpor occasioned by cold; or one end of the intestinal canal may become strengthened, and regain its peristaltic motion by reverse sympathy, when the other end is rendered torpid by ice-water. (Pomme des Affections Vaporeuses, p. 25.) These remove the present symptoms; and bark, steel, exercise, coldish bath, prevent their returns. See Art. VI. 2. 1.

Vol. II. T II. Hydrophobia.

mad-dog, is a violent inversion of the motions of the cesophagus on the contact or even approach of water or other studies. The pharynx seems to have acquired the sensibility of the larynx in this disease, and is as impatient to reject any sluid which gets into it. Is not the cardia ventriculi the seat of this disease? As in cardialgia the pain is often selt in the pharynx, when the acid material stimulates the other end of the canal, which terminates in the stomach. As this satal disease resembles tetanus, or locked jaw, in its tendency to convulsion from a distant wound, and affects some other parts by association, it is treated of in Class III. 1. 1. 15. and IV. 2. 1. 7.

M. M. I should recommend the trial of one grain and a half of corrosive sublimate of mercury, hydrargyrus muriatus, disfolved in half an ounce of rectified spirit of wine, to be given undiluted, if possible, as described in Class II. 1. 5. 1. and to be

repeated according to its operation.

ORDO III.

Retrograde Irritative Motions.

GENUS II.

Of the Absorbent System.

SPECIES.

at defluxion of a thin fluid from the nostrils, for a few hours, occasioned by the retrograde motions of their lymphatics; which may probably be supplied with sluid by the increased absorption of some other lymphatic branches in their vicinity. It is distinguished from that mucous discharge, which happens in frosty weather from decreased absorption, because it is less salt to the taste; and from an increased secretion of mucus, because it is neither so visited, nor is attended with heat of the part. This complaint is liable to recur at diurnal periods, like an intermittent fever, for weeks and months together, with great sneezing and very copious discharge for an hour or two.

I have feen two of these cases, both of which occurred in delicate women, and seemed an appendage to other hysteric symptoms; whence I concluded, that the discharge was occasioned by the inverted motions of the lymphatics of the nostrils, like the pale urine in hysteric cases; and that they might receive this shuid from some other branches of lymphatic vessels opening into

the frontal or maxillary cavities in their vicinity.

Could fuch a discharge be produced by strong errhines, and excite an absorption of the congestion of lymph in the dropsy of the brain?

2. Salivatio lymphatica. Lymphatic falivation. A copious expuition of a pellucid infipid fluid, occasioned by the retrograde motions of the lymphatics of the mouth. It is fometimes periodical, and often attends the hysteric disease, and nervous severs; but is not accompanied with a faline taste, or with heat of the

mouth, or nausea.

3. Nausea humida. Moist nausea consists in a discharge of fluid, owing to the retrograde motions of the lymphatics about the fauces, without increase of heat, or faline taste, together with some retrograde motions of the fauces or pharynx along with this nausea, a sickness generally precedes the act of vomiting; which may consist of a similar discharge of mucus or chyle

into the stomach by the retrograde motions of the lymphatics or lacteals, which open into it. See Class I. 2. 4. 3. and I. 2. 4. 4. M. M. Subacid liquids. Wine. Opium. A blister.

- 4. Diarrhæa lymphatica. Lymphatic diarrhœa. A quantity of mucus and lymph are poured into the intestines by the inverted motions of the intestinal lymphatics. The feces are less fetid and more liquid; and it sometimes portends the commencement of a diabetes, or dropfy, or their temporary relief. This lymphatic diarrhœa sometimes becomes chronical, in which the atmospheric moisture, absorbed by the cutaneous and pulmonary lymphatics, is poured into the intestines by the retrograde motions of the lacteals. See Section XXIX. 4. 6. where some cases of this kind are related.
- 5. Diarrhea chylifera, celiaca. Chyliferous diarrhea. The chyle drunk up by the lacteals of the upper intellines is poured into the lower ones by the retrograde motions of their lacteals, and appears in the dejections. This circumstance occurs at the beginning of diarrhea crapulosa, where the patient has taken and digested more aliment than the system can conveniently receive, and thus eliminates a part of it; as appears when there is curdled chyle in some of the dejections. See Sect. XXIX. 4. 7. It differs from the lymphatic diarrhea, as the chyliferous diabetes differs from the aqueous and mucaginous diabetes.

6. Diabetes. By the retrograde motions of the urinary lymphatics, an immense quantity of sluid is poured into the bladder. It is either termed chyliferous, or aqueous, or mucaginous, from the nature of the sluid brought into the bladder; and is either a temporary disease, as in hysteric women, in the beginning of intoxication, in worm cases, or in those exposed to cold damp air, or to great fear, or anxiety, or in the commencement of some

dropfies; or it becomes chronical.

When the urinary lymphatics invert their motions, and pour their refluent contents into the bladder, fome other branch of the abforbent fystem acts with greater energy to supply this fluid. If it is the intestinal branch, the chyliferous diabetes is produced: if it is the cutaneous or pulmonary branch, the aqueous diabetes is produced: and if the cellular or cystic branches, the mucaginous diabetes. In the two last the urine is pellucid, and contains no sugar.

In dropfies the fluid is fometimes abforbed, and poured into the bladder by the retrograde motions of the urinary lymphatics, as during the exhibition of digitalis. In the beginning of the dropfies of infirm gouty patients, I have frequently observed, that they make a large quantity of water for one night, which relieves them for several days. In these cases the patient previoully feels a fulnels about the præcordia, with difficult respiration, and symptoms similar to those of hysteria. Perhaps a previous desect of absorption takes place in some part of the body in those hysteric cases, which are relieved by a copious discharge of pale urine. See Diabetes explained at large, Section XXIX. 4.

A discharge of blood sometimes attends the diabetes, which was occasionally a symptom of that disease in Mr. Brindley, the great navigable canal maker in this country. Which may be accounted for by the communication of a lymphatic branch with the gastric branch of the vena portarum, as discovered by J. F. Meckel. See Section XXVII. 2.

M. M. Alum. Earth of alum. Cantharides. Calomel.

Bark. Steel. Refin. Opium. See Sect. XXIX. 4.

Since the publication of the first edition of this work, I have seen two patients affected with diabetes, who were both of them between fixty and seventy years old, and had formerly lived rather freely, though very temperately latterly for many years. The water they made had not been accurately measured or evaporated; but one of them observed that his terrier bitch lapped his urine in large quantities, and preferred it much to common water; whence he concluded, it must contain some nutritious matter.

They both complained of thirst, and had drunk two or three times as much as usual, during the time they had been affected with the diabetes; which was about four months in one, and about three in the other. As I esteemed these cases to be owing to the patients swallowing more sluid than could be so hastily taken into the circulation, and that therefore a part of it was conveyed to the bladder by the retrograde action of the lymphatics, as in the beginning of intoxication; I prevailed on them to drink no more than their usual quantity, or less; and both these mild cases of diabetes ceased immediately by this simple treatment of them.

A fimilar event feems to have existed in the two cases of diabetes first published by Dr. Rollo; on those days the patients drank but little, the quantity of urine was not more than natural. Both from these cases, and from others related by Dr. Rollo, it appears, that when the patient lived on animal food, less faccharine matter was detected in the urine, and also that the quantity of the urine abated; the former of these circumstances is readily accounted for, as vegetable materials are probably more copiously convertible into sugar, either chemically or by the power of digestion, than animal materials; and the latter seems probably owing to the patients drinking less in quantity, when they were restrained from beer and milk, and were allowed only broth in their stead.

In the case from Liverpool, published by Dr. Rollo, the patient did not weigh heavier after sitting ten minutes in a bath of 110 degrees of heat; which shews that no part of the diabetic urine was owing to increased cutaneous absorption, and that this disease was not the aqueous but the chyliserous diabetes; and I suppose the patient's weighing heavier or not after using a warm bath may depend on the quantity of fluid previously taken by the mouth; as the skin may thence be either in an absorbent or exhalent state, and owing to a greater or less degree of heat, which may render the quantity of perspiration in the bath greater than the quantity absorbed. See Sect. XXIX. 4.5.

7. Sudor lymphaticus. Profuse sweats from the inverted motions of the cutaneous lymphatics, as in some fainting sits, and at the approach of death; and as perhaps in the sudor anglicanus. See Sect. XXIX. 5. These sweats are glutinous to the touch, and without increased heat of the skin; if the part is not covered, the skin becomes cold from the evaporation of the sluid. These sweats without heat sometimes occur in the act of vomiting, as in Sect. XXV. 9. and are probably the cause of the cold sweaty hands of some people. As mentioned in Sect. XXIX. 4. 9. in the case of R. Davis, which he cured by frequent application of time. Though it is possible, that cold sweaty hands may also arise from the want of due absorption of the perspirable matter effused on them, and that the coldness may be owing to the greater evaporation in consequence.

The acid fweats described by Dr. Dobson, which he observed in a diabetic patient, and ascribes to the chyle effused on the skin, must be ascribed to the retrograde action of the cutaneous

lymphatics. See Sect. XXIX. 6.

8. Sudor afthmaticus. The cold sweats in this disease only cover the head, arms, and breast, and are frequently exceedingly profuse. These sweats are owing to the inverted motions of the cutaneous lymphatics of the upper part of the body, and at the fame time the increased absorption of the pulmonary absorbents: hence these sweats when profuse relieve the present fit of althma. There is no other way to account for sweats appearing on the upper parts of the body only, but by the fluid having been absorbed by the lymphatic branch of the lungs, and effused on the skin by the retrograde movements of the cutaneous lymphatics; which join those of the lungs before they enter into the venous circulation. For if they were occasioned, as generally supposed, by the difficulty of the circulation of the blood through the lungs, the whole skin must be equally affected, both of the upper and lower parts of the body; for whatever could obstruct the circulation in the upper part of the venous system, must equally obstruct it in the lower part of it. See Sect. XXIX.

6. In the convulsive asthma these sweats do not occur; hence they may be distinguished; and might be called the hydropic

asthma, and the epileptic asthma.

o. Translatio puris. Translation of matter from one part of the fystem to another can only be explained from its being abforbed by one branch of the lymphatic fystem, and deposited in a diffant part by the retrograde motions of another branch; as mentioned Sect. XXIX. 7. 1. It is curious, that thefe translations of matter are attended generally, I believe, with cold fits; for less heat is produced during the retrograde action of this part of the fystem, as no fecretion in the lymphatic glands of the affected branches can exist at the same time. Do any ineffectual retrograde motions occasion the cold fits of agues? The time when the gout of the liver ceases, and the gout in the foot commences, is attended with a cold fit, as I have observed in two instances, which is disficult to explain, without supposing the new vessels, or the matter produced on the inflamed liver, to be absorbed, and either eliminated by some retrograde motion, or carried to the newly inflamed part? See Class IV. 1. 2. 15.

10. Translatio lactis. Translation of milk to the bowels in puerperal fevers can only be explained by the milk being absorbed by the pectoral branch of lymphatics, and carried to the bowels by the retrograde motions of the intestinal lymphatics or lacteals. See many instances of this in Sect. XXIX. 7. 4.

ous case related in the Transactions of the College of Physicians at Philadelphia, Vol. I. p. 96. of a girl, who labouring under an ischuria vomited her urine for many months; which could not be distinguished from that which was at other times drawn off by the catheter. After having taken much opium, she seems at length to have formed gravel, some of which was frequently brought up by vomiting. Dr. Senter ascribes this to the retrograde motions of the lymphatics of the stomach, and the increased ones of those of the bladder, and refers to those of Sect. XXIX. of this work; which section was first published in 1780; and to Macquer's Dictionary of Chemistry, Art. Urine.

The patient above described sometimes had a discharge of urine by the navel, and at other times by the rectum, and some-

times by urinous fweats.

ORDO III.

Retrograde Irritative Motions.

GENUS III.

Of the Sanguiferous System.

SPECIES.

1. Capillarium motus retrogressis. In microscopic experiments it is usual to see globules of blood regurgitate from the capillary vessels again and again, before they pass through them; and not only the mouths of the veins, which arise from these capillaries, are frequently seen by microscopes to regurgitate some particles of blood during the struggles of the animal; but a retrograde motion of the blood in the veins of these animals, from the very heart to the extremities of the limbs, is observable by intervals during the distresses of the dying creature. Haller, Elem. Phys. T. 1. p. 216. See Section XXIX. 2. 8.

2. Palpitatio cordis. May not the ineffectual and weak unequal motions of the heart in hysteric cases be ascribed to the retrograde motions of it, which continue for a short time, or ter-

minate in fyncope? See Class IV. 3. 1. 6.

3. Anhelatiospasmodica. In some asthmas may not the difficulty of respiration arise from the inverted action of the finer branches of the bronchia, or of the pulmonary artery or vein, like those of the capillaries above described in No. 1. of this genus?

DISEASES OF SENSATION.

ORDO I.

Increased Sensation.

GENUS I.

With increased Action of the Muscles:

THE actions belonging to this genus are those which are immediately excited by the sensations of pain or pleasure, but which are neither followed by inflammation nor by convulsion. The former of which belong to the subtequent genera of this

order, and the latter to the class of voluntary motions.

The criterion between the actions, which are the immediate confequence of painful fensation, and convulsive actions properly so called, consists in the former having a tendency to dislodge the stimulating cause, which induces the painful sensation; and the latter being exerted for the purpose of expending the sensorial power, and thus dulling or destroying the general sensation of the system. See Class III. 1.

There is a degree of heat produced in the affected part by these sensitive actions without inflammation, but in much let's quantity than when attended by inflammation; as in the latter there is production of new vessels. See Sect. XXXIII. 2. 3.

Some of the species of this genus cannot properly be termed diseases in their natural state, but become so by their defect or excess, and are here inserted to facilitate the explanation of the others.

SPECIES.

1. Deglutitio. Swallowing our food is immediately caused by the pleasurable sensation occasioned by its stimulus on the palate or fauces, and is acquired long before the nativity of the animal. Afterwards the pain of hunger previously produces the various voluntary exertions to procure the proper material, but the actions of masticating and of swallowing it are effected by the sensor procure of sensation; which appears by their not being always controlable by the will, as when children in vain attempt to swallow nauseous drugs. See Class IV. 1. 3. 1.

The masticated food stimulates the palate, which is an organ of fense, into so much action, as to produce agreeable sensation; and the muscles subservient to deglutition are brought into action by the sensation thus produced. The pleasurable sensation is the proximate cause; the action of the sibres of the extremities of the nerves of taste is the remote cause; the sensor it taste into increased action is the pre-remote cause; the action of the muscles of deglutition is the proximate effect; the pushing the food into the stomach is the remote effect; and the nutrition

of the body is the post-remote effect.

Though the muscles subservient to deglutition have their actions previously affociated, so as to be excited into synchronous tribes or successive trains, either by volition, as when we swallow a disagreeable drug; or by sensation, as when we swallow agreeable food; or by irritation, as when we inattentively swallow our faliva; yet do all those three kinds of deglutition belong to the respective classes of volition, sensation, and irritation; because the first links of these tribes or trains of muscular action are excited by those sensors and the associated links, which accompany or succeed them, are excited by the combined powers either of volition, or of sensation, or of irritation, along with that of association.

2. Respiratio. Respiration is immediately caused by the senforial power of sensation in consequence of the baneful want of vital air; and not from the accumulation of blood in the lungs, as that might be carried on by inhaling azote alone, without the oxygenous part of the atmosphere. The action of respiration is thus similar to that of swallowing our food to appease the pain of hunger; but the lungs being surrounded with air, their proper pabulum, no interimmediate voluntary exertions are required, as in hunger, to obtain and prepare the wanted material.

Respiration is similar to slow combustion; the oxygenous part of the atmosphere is received through the moist membranes, which line the air-cells of the lungs, and uniting with the inflammable part of the blood generates an acid, probably the phosphoric acid; a portion of carbonic acid is likewise produced in this process; as appears by repeatedly breathing over lime water, which then becomes turbid. See Botanic Garden,

P. I. Canto I. 1. 401. note.

3. Sternutatio. Sneezing confifts of muscular actions produced by the sensorial faculty of fensation; and is an effort to dislodge, by means of air forcibly impelled through the nostrils, some material; which stimulates the membrane, which lines

them, into too great action, and might thence injure the fense of fmell which is diffused on it.

In this operation the too great action of the vessels of the membrane of the nostrils is the remote cause; the sensation thence induced is the proximate cause; and the muscular actions are the proximate effect.

This action of ineezing frequently precedes common respiration in new-born children, but I believe not always; as like the latter it cannot have been previously acquired in the uterus.

It is produced in some people by sudden light, as by looking up at the sky in a morning, when they come out of a gloomy bed-chamber. It then becomes an affociate action, and belongs to Class IV. 14 2. 2.

M. M. When it is exerted to excess it may be cured by

fnuffing starch up the nostrils. See Class I. 1. 2. 13.

4. Anhelitus. Panting. The quick and laborious breathing of running people, who are not accustomed to violent exercise, is occasioned by the too great conflux of blood to the lungs. As the fanguiferous fystem, as well as the absorbent system, is furnished in many parts of its course with valves, which in general prevent the retrograde movement of their contained sluids; and as all these vessels, in some part of their course, lie in contact with the muscles, which are brought into action in running, it follows that the blood must be accelerated by the intermitted swelling of the bellies of the muscles moving over them.

The difficulty of breathing, with which very fat people are immediately affected on exercise, is owing to the pressure of the accumulated fat on the veins, arteries, and lymphatics; and which, by diffending the skin, occasions it to act as a tight bandage on the whole furface of the body. Hence when the muscles are excited into quicker action, the progress of the blood in the veins, and of the lymph and chyle in the absorbent system, is urged on with much greater force, as under an artificial bandage on a limb, explained in Art. IV. 2. 10. and in Scot. XXXIII. 3. 2. Hence the circulation is infantly quickened to a great degree, and the difficulty of breathing is the confequence of a more rapid circulation through the lungs. The increased fecretion of the perspirable matter is another consequence of this rapid circulation; fat people, when at rest, are believed to perfpire less than others, which may be gathered from their generally having more liquid stools, more and paler urine, and to their frequently taking less food than many thin people; and lastly, from the perspiration of fat people being generally more inodorous than that of lean ones; but when corpulent people are put in motion, the sweat stands in drops on their skins, and they VOL. II.

lard the ground" as they run. The increase of heat of corpulent people on exercise, is another consequence of their more rapid circulation, and greater secretion. See Class I. 2. 3. 17.

Other causes of difficult or quick respiration will be treated

of under Asthma, Pertussis, Peripneumonia, Tonsillitis.

5. Tuffis ebriorum. Sensitive cough is an exertion of the muscles used in expiration excited into more violent action by the sensorial power of sensation, in consequence of something which too powerfully stimulates the lungs. As the saline part of the secreted mucus, when the absorption of it is impeded; or the too great viscidity of it, when the absorption is increased; or the too great quantitity of the mucus, when the secretion is increased; or the inflammation of the membranes of the lungs; it is an effort to dislodge any of these extraneous materials.

Of this kind is the cough which attends free-drinkers after a debauch; it confifts of many short efforts to cough, with a frequent expuition of half a tea-spoonful of frothy mucus, and is attended with confiderable thirst. The thirst is occasioned by the previous diffipation of the aqueous parts of the blood by fenfible or infenfible perspiration; which was produced by the increafed action of the cutaneous and pulmonary capillaries during the stimulus of the wine. In consequence of this an increased absorption commences to replace this moisture, and the skin and mouth become dry, and the pulmonary mucus becomes infpiffated; which stimulates the bronchia, and is raised into froth by the fuccessive currents of air in evacuating it. This production of froth is called by fome free-drinkers "fpitting fixpences" after a debauch. This subsequent thirst, dry mouth, and viscid expectoration in some people succeeds the slightest degree of intoxication, of which it may be esteemed a criterion. See Class IV. 2. 1. 8.

As coughs are not always attended with pain, the muscular actions, which produce them, are sometimes excited by the senforial faculty of irritation, as in Class I. 1. 2. 8. I. 1. 3. 4.
I. 1. 4. 3. I. 2. 3. 4. Coughs are also sometimes convulsive,
as in Class III. 1. 10. and sometimes sympathetic, as in Class
IV. 2. 1. 7.

M. M. Venesection, when the cough is attended with inflammation. Mucillages. Opium. Torpentia. Blifter.

6. Singultus. Hiccough is an exertion of the muscles used in inspiration excited into more violent action by the sensorial power of sensation, in consequence of something which too powerfully stimulates the cardia ventriculi, or upper orifice of the stomach. As when solid food is too hastily taken without sufficient dilution. And is an effort to dislodge that offensive material.

rial, and push it to some less sensible part of the stomach, or into the middle of the contained aliment.

At the end of fatal fevers it may arise from the acrimony of the undigested aliment, or from a part of the stomach being already dead, and by its weight or coldness affecting the surviving part with disagreeable sensation. The pain about the upper orifice of the stomach is the proximate cause, the too great or too little action of the sibres of this part of the stomach is the remote cause, the action of the muscles used in inspiration is the proximate effect, and the repercussion of the offending material is the remote effect.

Hiccough is fometimes fympathetic, occasioned by the pain of gravel in the kidney or ureter, as in Class IV. 1. 1. 7. and is fometimes a symptom of epilepsy or reverie, as in Sect. XIX. 2.

M. M. Oil of cinnamon from one drop gradually increased

to ten, on fugar, or on chalk. Opium, Blifter. Emetic.

7. Crapula ventriculi. Indigestible substances in the stomach. This frequently occurs in children, who are restrained by their ill-active friends from fruit or other sweet things; and thus the rational mind is taught to superintend the satiety of the sensation of the sense of hunger, or of the pleasure of the palate, which is contrary to nature, and a much more erroneous guide. Hence children are liable to swallow more plums and cherries than their stomachs can digest; and if these run hastily into fermentation, much air, or gas, is generated; and produces an inconvenient distention of the stomach, as well as a disagreeable sensation, which generally terminates in ejecting the offending matter by vomiting.

In cows which have eaten too much young clover, the faccharine and mucilaginous matter, which it contains, runs into fo violent fermentation as by differnion to destroy the animal. Whence it has been customary with some to perforate the first stomach, and thus let out the air. Dr. White, of Edinburgh, afferted, that he witnessed about twenty beasts in this situation, two were dead before the medicine could be administered, but to the other eighteen he directed half a pint of spirits, called gin or whisky, mixed with as much water, to be given; and they all parted with much air by eructation, and recovered. An ingenious gentleman has lately put a slexible pipe down the esophagus into the distended stomach of these animals with certain success, as related in some late publication. A slexible tube for this purpose might be made of wire wrapped round a stick about half an inch in diameter, and afterwards covered with leather.

A boy about 8 years old swallowed a halfpenny, which was believed to pass through him at school, some weeks afterwards,

but he has not recovered his health. I was informed, that an idiot had swallowed a half-crown piece, and directed crude quickfilver to be given him in repeated quantities, but never heard the event of the cafe.

A lady in my presence was eating a custard out of a tea-cup. and put 3 or 4 pins into her mouth, which were supposed to have been carelessly left in the cup, and swallowed one of them: now, though needles have found their way out of the body, and other tharp indigestible materials, yet pins being terminated with heads are faid often to have occasioned dangerous and painful difeases, and sometimes death. What then should be done? It occurred to me, that as the head of the pin would have fo much greater friction than the point, that if it was carried forwards by a stream of mucilaginous fluid, the head must go first; and I therefore immediately directed an emetic, and the pin was brought up without any pain, or any stains of blood in the ejected fluid.

8. Afilma humorale. The humoral afthma probably confifts in a temporary analarca of the lungs, which may be owing to a temporary defect of lymphatic absorption. Its cause is nevertheless at present very obscure, since a temporary deficiency of venous abforption, at the extremities of the pulmonary or bronchial veins, might occasion a fimilar difficulty of respiration. See Abortio, Class I. 2. 1. 14. Or it might be supposed, that the lymph effused into the cavity of the chest might, by some additional heat during fleep, acquire an aerial form, and thus comprefs the lungs; and on this circumstance the relief, which these patients receive from cold air, would be readily accounted for.

The paroxysms attack the patient in his first sleep, when the circulation through the lungs in weak people wants the affiftance of the voluntary power. Class I. 2. 1. 3. And hence the abforbents of the lungs are less able to fulfil the whole of their duty. And part of the thin mucus, which is fecreted into the air-cells, remains there unabforbed, and occasions the difficult respiration, which awakes the patient. And the violent exertions of the muscles of respiration, which succeed, are excited by the pain of fuffocation, for the purpose of pushing forwards the blood through the compressed capillaries, and to promote the abforption of the effused lymph.

In this the humoral differs from the convultive afthma, treated of in Class III. 1. 10. as in that there is probably no accumulated fluid to be absorbed; and the violent respiration is only an exertion for the purpose of relieving pain, either in the lungs or in some distant part, as in other convulsions, or epilepsy; and in this respect the fits of humoral and convulsive asthma effentially differ from each other, contrary to the opinion expressed without sufficient consideration in Sect. XVIII. 15.

The patients in the paroxysms both of humoral and convulsive asthma find relief from cold air, as they generally rise out of bed, and open the window, and put out their heads; for the lungs are not sensible to cold, and the sense of suffocation is somewhat relieved by there being more oxygen contained in a given quantity of cold fresh air, than in the warm confined air of a close bed-chamber.

I have feen humoral afthma terminate in confirmed anafarca and destroy the patient, who had been an excessive drinker of spirituous potation. And M. Savage afferts, that this disease frequently terminates in diabetes; which seems to shew, that it is a temporary dropfy relieved by a great flow of urine. Add to this, that these paroxysms of the asthma are themselves relieved by profuse sweats of the upper parts of the body, as explained in Class I. 3. 2. 8. which would countenance the idea of their be-

ing occasioned by congestions of lymph in the lungs.

The congestion of lymph in the lungs from the desective abforption of it is probably the remote cause of humoral asthma;
but the pain of suffocation is the immediate cause of the violent
exertions in the paroxysms. And whether this congestion of
lymph in the air-cells of the lungs increases during our sleep, as,
above suggested, or not; the pain of suffocation will be more
and more distressing after some hours of sleep, as the sensibility
to internal stimuli increases during that time, as described in
Sect. XVIII. 15. For the same reason many epileptic sits, and

paroxyims of the gout, occur during fleep.

In two gouty cases, complicated with jaundice, and pain, and sickness, the patients had each of them a shivering sit, like the commencement of an ague, to the great alarm of their friends; both which commenced in the night, I suppose during their sleep; and the consequence was a cestation of the jaundice, and pain about the stomach, and sickness; and instead of that the gout appeared in their extremities. In these cases I conjecture, that there was a metastasis not only of the diseased action from the membranes of the liver to those of the foot; but that some of the new vessels, or new sluids, which were previously produced in the instanced liver, were translated to the feet during the cold sit, by the increased absorption of the hepatic lymphatics, and by the retrograde motions of those of the affected limbs.

This I think refembles in some respects a sit of humoral asthma, where stronger motions of the absorbent vessels of the lungs are excited, and retrograde ones of the correspondent cutaneous lymphatics; whence the violent sweats of the upper parts of the

body

body only are produced; and for a time the patient becomes relieved by the metastasis and elimination of the offending material by sensitive exertion. For a surther account of this intricate subject see Class III. 1. 10.

M. M. To relieve the paroxysm a tea-spoonful of ether may be given mixed with water, with 10 drops of laudanum, to be repeated three or four times. Venesection. An emetic. A blister. Afterwards the Peruvian bark, with a grain of opium at night, and two or three of aloes. A slannel shirt in winter

but not in fummer. Issues. Digitalis?

In this species of asthma, there is great reason to believe, that the respiration of an atmosphere, with an increased proportion of oxygen, will prove of great advantage; some well observed and well attested cases of which are published by Dr. Beddoes; as this purer air invigorates the circulation, and the whole system in consequence, perhaps not only by its stimulus, but by its supplying the material from which the sensorial power is extracted or fabricated. In spasmodic asthma, on the contrary, Dr. Ferriar has found undoubted benefit from an atmosphere mixed with hydrogen. See Sect. XVIII. 15. and Class III. 1. 10.

9. Nictitatio fenfitiva. Winking of the eyes is performed every minute, without our attention, for the purpose of diffusing the tears over them, which are poured into the eye a little above the external corner of it, and which are afterwards absorbed by the lachrymal points above and below the internal corner of it. When this operation is performed without our attention, it is caused by the faculty of irritation, and belongs to Class I. 1. 4. 1. but when it is produced by a stronger stimulus of any extrancous material in the eye, so as to cause pain, the violent and fre-

quent nictitation is caused by the faculty of sensation.

This difease is sometimes produced by the introversion of the edge of the lower eyelid, which bends the points of the hairs of the eyelash upon the ball of the eye, which perpetually stimulate it into painful sensation. This introversion of the eyelid is generally owing to a tumour of the cellular membrane below the edge of the eyelid, and though a very troublesome complaint may often be cured by the following simple means. A little common plaster spread on thin linen, about a quarter of an inch long, must be rolled up so as to be about the fize of a crow-quill; this must be applied immediately below the eyelash on the outside of the eye, and must be kept on by another plaster over it. This will then act as a slight compression on the tumor under the eyelash, and will prevent the hairs from touching the eyeball. In a week or two the compression will diminish the tumor it lies over, and cure this painful deformity.

10. Oscitatio

ro Oscitatio et pandiculatio. Yawning and stretching of the limbs is produced either by a long inactivity of the muscles now brought into action, as sometimes happens after sleep, or after listening a long time to a dull narrative; or it is produced by a too long continued action of the antagonist muscles. In the former case there is an accumulation of sensorial power during the quiescence of the muscles now brought into action; which probably constitutes the pain or wearisomeness of a continued attitude. In the latter case there is an exhaustion of sensorial power in the muscles, which have lately been acting violently, and a consequent accumulation in the muscles, which are antagonists to them, and which were at rest.

These involuntary motions are often seen in paralytic limbs, which are at the same time completely disobedient to the will; and are frequently observable in very young children; and from thence we may conclude, that these motions are learnt before nativity; as puppies are seen to open their mouths before

the membranes are broken. See Sect. XVI. 2.

Where these motions are observed in limbs otherwise paralytic, it is an indication that electric shocks may be employed with advantage, as the excitability of the limb by irritation is not extinct, though it be disobedient both to volition and sensation.

11. Tenefinus confifts in violent and frequent ineffectual efforts to discharge the contents of the rectum, owing to pain of the sphincter. The pain is produced by indurated seces, or by some acrid material, as the acidity of indigested aliment; and the efforts are attended with mucus from the pained membrane. The seces must sometimes be taken away by the end of a marrow-spoon, as cathartics and even clysters will pass without removing them. It is sometimes caused by sympathy with the urethra, when there is a stone at the neck of the bladder. See Class II. 2. 2. 7. and IV. 1. 2. 8.

M. M. Fomentation, an enema with mucilage and laudanum. The common exclusion of the feces from the rectum is a process similar to this, except that the muscles of the sphincter ani, and those of the abdomen, which act along with them by the combined powers of sensation and affociation, are in tenesmus excited by painful sensation, and in the latter by a sensation, which may in some instances be almost called pleasurable, as relieving us from a painful one in the exclusion of the seces.

12. Stranguria. Strangury confifts in painful efforts to discharge the contents of the urinary bladder. It is generally owing to a stone in the sphincter of the bladder; or to the instammation of the neck of it occasioned by cantharides. It is sometimes caused by sympathy with the piles; and then is liable in

women to occasion convulsions, from the violence of the pain without inflammation. See Class IV. 2, 2, 2, and 3.

M. M. Fomentation clyster with oil and laudanum, push the stone back with a bougie; if from cantharides, give half a pint of warm water every ten minutes. Mucilage of gum arabic and

tragacanth.

The natural evacuation of the urine is a process similar to this, except that the muscular fibres of the bladder, and the muscles of the abdomen, which act in concert with them by the combined powers of sensation and of association, are, in the former case of strangury, excited into action by painful sensation; and in the latter by a sensation, which may almost be termed pleasurable, as it relieves us from a previous uneasy one.

The ejectio feminis is another process in some respects similar to strangury, as belonging to the same sensible canal of the urethra, and by exciting into action the acceleratory muscles; but in the strangury these muscles are excited into action by painful fensation, and in the ejection of the semen by pleasurable sensa-

tion.

13. Parturitio. Parturition is not a difease, it is a natural process, but is more frequently unfortunate in high life than amongst the middle class of females; which may be owing partly to fear, with which the priests of LUCINA are liable to inspire the ladies of fashion to induce them to lie-in in town; and partly to the bad air of London, to which they purposely resort.

There are however other causes, which render parturition more dangerous to the ladies of high life; such as their greater general debility from neglect of energetic exercise, their inexperience of the variations of cold and heat, and their seclution from fresh air. To which must be added, that great source of the destruction of semale grace and beauty, as well as of semale health, the tight stays and other bandages, with which they are generally tortured in their early years by the active folly of their friends, which by displacing many of the viscera impedes their actions, and by compressing them together produces adhesions of one part to another, and affects even the form and aperture of the bones of the pelvis, through which the nascent child must be protruded.

As parturition is a natural, not a morbid process, no medicine should be given, where there is no appearance of disease. The absurb custom of giving a powerful opiate without indication to all women, as soon as they are delivered, is, I make no doubt, frequently attended with injurious, and sometimes with satal

consequences. See Class II. 1. 2. 16.

Another thing very injurious to the child, is the tying and

cutting the navel-string too soon; which should always be left till the child has not only repeatedly breathed, but till all pulsation in the cord ceases. As otherwise the child is much weaker than it ought to be; a part of the blood being left in the placenta, which ought to have been in the child; and at the same time the placenta does not so naturally collapse, and withdraw itself from the sides of the uterus, and is not therefore removed with so much safety and certainty. The folly of giving rue or rhubarb to new-born children, and the danger of seeding them with gruel instead of milk, is spoken of in Class I. 1. 2. 5. and II. 1. 2. 16.

Many ladies become diseased by an unnatural resusal of giving suck to their child, which ought to relieve their breasts of the load of milk, and give consolation to their minds by the storge or love to their infant. Many ladies indeed experience a dissinculty in nursing their children from their not having nipples to their breasts; which have been often instanced and destroyed in their early years, even in their insancy, as I have seen, by the hard edge of stiff stays rubbing against them, and sometimes, I

believe, by the fmall-pox.

M. Herholdt, of Copenhagen, has announced a discovery which he thinks highly interesting to humanity; which is, that the apparent death of new-born infants arises from the trachea, or wind-pipe, being silled with water; and that they may be generally saved by giving them such an inclined position, that the water may run out. Of thirteen children, which were supposed to be dead or still-born, he says, that twelve recovered by these simple means. As the trachea may not have acquired due sensibility before delivery, in some feeble or premature births, this circumstance may possibly arise, though it seldom occurs even in drowned people. Medical Review, July, 1799.

Vol. II. X ORDO

ORDO I.

Increased Sensation.

GENUS II.

With the Production of new Vessels by internal Membranes or Glands, with Fever.

In the first class of diseases two kinds of severs were described, one from excess, and the other from desect of irritation; and were in consequence termed irritative, and inirritative severs. In this second class of diseases another kind of sever occurs, which is caused by excess of sensation, and termed in consequence Sensitive Fever. But there is no sever from desect of sensation, because the circulation is carried on in health without our consciousness, that is, without any sensation attending it.

But as excefs of fensation may exist with excess or defect of irritation, two other kinds of fever arise from a combination of fensitive fever with the irritative, and inirritative ones. Making

five kinds in all.

1. Irritative fever, described in Class I. 1. 1.

2. Inirritative fever. Class I. 2. 1. 1.

3. Sensitive fever. Class II. 1. 6. 1.

4. Sensitive irritated fever. Class II. 1. 2. 1. 5. Sensitive inirritated fever. Class II. 1. 3. 1.

As the fensitive irritated fever attends all the diseases enumerated under the genus about to be described, it is placed at the head of it. And as the sensitive inirritated sever accompanies the greatest number of the species enumerated under the third genus of this order, it is placed at the head of them. And as the sensitive sever attends the diseases of the sixth genus, it is placed at the head of them. But as every febrile paroxysin consists of disordered tribes or trains of associated motions, it may be doubted, whether they ought not all to have been placed in the fourth class, amongst the diseases of association. See Class IV. 2. 4. 11.

All the subsequent species of this genus are attended with senfitive irritated sever; there are nevertheless some superficial inflammations, which affect the same situations without much sever, as the scrosulous ophthalmy and spurious peripneumony,

which belong to other genera.

Inflammation is uniformly attended with the production or fecretion of new fibres conftituting new veffels; this therefore

may be esteemed its essential character, or the criterion of its existence. The extension of the old vessels seems rather a confequence than a cause of the germination, or pullulation, of these new ones; for the old vessels may be enlarged, and excited with unusual energy, without any production of new ones, as in the

bluth of thame or of anger.

When these new veisels are formed, if they are not reabforbed into the circulation, they secrete a new sluid called purulent matter; which generally opens itself a passage on the external skin, and produces an ulcer, which either gradually heals, or spreads, and is the cause of hectic sever; or they secrete contagious matter, which has the property of exciting the same kind of inflammation, and of producing the same kind of contagious matter, when inserted by inoculation into the skin of other persons. These contagious matters form ulcers, which either heal spontaneously, or by art; or continue to spread, and destroy the patient, by other kinds of hectic sever.

In this genus there is an increase of the sensorial power of irritation as well as of sensation; whence great arterial energy is produced, and the pulse becomes strong and sull, as well as quick; and the coats of the arteries seel hard under the singer, being themselves thickened and distended by inflammation. The blood drawn, especially at the second bleeding, is covered with a tough size; which is probably the mucus from the inslamed internal surface of the arteries, increased in quantity, and more coagulable than in its natural state; the thinner part being more

perfectly absorbed by the increased action of the inflamed absorbents. See Sect. XXXIII. 2. 2. This is rendered more probable, because the hard feel of the pulse, and the abundance of

coagulable lymph commence, exist, and cease together.

Great heat is produced from the new chemical combinations arising in the fecretion of new fibres, and great pain from the diffention of old ones, or from their increased action. The increased quantity of fensation from a topical inflammation or phlegmon is the immediate cause of the febris sensitiva irritata, or inflammatory sever; as when it arises from the pain of pleurisy, or paronychia; but generally an irritative sever precedes this topical inflammation, which occurs during the hot sit of it; and then the irritative sever is changed into a sensitive irritated sever, by the additional cause of the sensorial power of sensation besides that of irritation.

SPECIES.

1. Febris fensitiva irritata. Sensitive irritated fever, or in-

flammatory fever. Phlegmana. A strong full pulse, with inflammation of the coats of the arteries, constitutes this disease. It originates from some topical inflammation, which, if the sever is not subdued, terminates in suppuration; and differs from irritative sever in respect to the painful sensation which accompanies it. For as pleasurable sensation is the cause of the growth of the new vessels, and distention of the old ones, in the natural enlargement of the body during our infancy; so a painful sensation is the cause of the unnatural production of new vessels, and enlargement of old ones in inflammatory diseases.

When matter is thus formed in any internal vifcus, or in the cellular membrane, as in the lungs or liver; fo long as this abscels remains without admission of air, this inflammatory fever is liable to continue, recieving only temporary relief by bleeding or emetics, or cathartics; till the patient, after a month, or two, or three, expires. But, if air be admitted to these internal abfceffes, this kind of fever is changed into a hectic fever in a fingle day. It also sometimes happens, that when the abscess remains unopened to the air, if the matter has become putrid, hectic fever supervenes, with colliquative sweats, or diarrhœa; the matter in both cases is sometimes absorbed, and the sides of the abscess grow together again without an external aperture. See Class II. 1. 4. 1. and 2. Another termination of inflammation is in gangrene, but this belongs to the inflammation of the external skin; as the production of purulent matter belongs to inflammation of the internal or mucous membranes. Thus when the external skin is the seat of inflammation, as in erythema, or eryfipelas, and produces fenfitive irritated fever, no collection of purulent matter can be formed; but a material oozes out, and lies upon the furface, like that in the confluent fmall-pox, and the cuticle at length peels off, or gangrene supervenes. It must be noted, that these kinds of inflammation can exist together; and some parts of the cellular membrane may suppurate at the same time that the external skin is affected with erythema, or ervfipelas.

M. M. Venesection. Cathartics. Diluents. Cool air.

Torpentia. Cold bath? See Sect. XII. 6.

The increased arterial action in this sensitive irritated fever is not simply owing to the increased irritability of the arterial system, or to the stimulus of the distention of the vessels, but also to the increased acrimony or pungency of the blood; which has now so far changed its nature as to become more sluid, more dense, and to be loaded with coagulable lymph. Hence it becomes necessary not only to lessen the quantity of blood by venesection and by cathartics, but also to dilute its acrimo-

ny, or pungency, by the introduction of aqueous and mucilaginous fluids, such as barley water, cream and water, sugar and water, weak broths; to which may be added so much of some vegetable essential oil, as may render them grateful to the stomach, and thus promote their absorption; as by infusing parsley or cellery and turnips in the broth; or by balm, mint, or sage teas.

The following species of this genus only distinguish the situation of the part previously inflamed, and which is the remote cause of the sensitive irritated, or inflammatory sever, which attends it.

2. Ophthalmia interna. Inflammation of the eye is attended with the production of new veffels, which spread over the tunica adjunctiva, and over the cornea; these new veffels are easily seen, as they lie on a white ground, and give ocular demonstration of their production in inflammation. When this inflammation of the cornea suppurates, it is liable to leave little ulcers, which may be seen beneath the surface in the form of little excavations; and as these heal, they are liable to be covered with an opaque scar. This scar, in some months or years, is liable to wear away, and become transparent, without the affistance of any polishing powder, as of very finely levigated glass, as some have recommended. But when the cornea is affected through all its thickness, the return of its transparency becomes hopeless. See Class I. 1. 3. 14.

In violent degrees of ophthalmy the internal parts, as the retina, optic artery, iris, ciliary process, become inflamed, as well as the external ones; hence the least light admitted to the eye occasions intolerable pain. This curious circumstance cannot be owing to the action of light on the inflamed vessels of the cornea; it therefore shews, that the extremity of the optic nerve or retina is also rendered more exquisitely sensible to light, by partaking of the inflammation; and I have been told, that red colours are in these cases sometimes painfully perceived even in perfect darkness. This shews that the retina is excited into motion by the stimulus of light; and that, when it is inflamed, these motions give great pain, like those of other inflamed parts, as the muscles, or membranes. And secondly, that the ideas of colours consist in the motions of the retina; which ideas occasion pain, when the extremity of the moving nerve is inflamed.

M. M. Venesection. Cathartics. Diluents. Torpentia. Frequently moisten the eye with cold water by means of a rag. Cool airy room. Darkness. When the inflammation begins to decline, white vitriol gr. vi. in an ounce of water is more essea-

cious to moisten the eye than folutions of lead. Tincture of opium diluted. Extract of belladonna. New vessels from the instance tunica adnata frequently spread like a fly's wing upon the transparent cornea, which is then called Pterigium. To stop the growth of this, the principal vessels should be cut through with a lancet. When the inflammation begins to decline, after due evacuation any stimulating material put into the eye increases the absorption, which soon removes the new red vessels; which has given rise to a hundred famous eye-waters, and eye-dostors; if these stimulating materials are used too soon, the inflammation is increased by them. See Sect. XXXII. 2. 10 Class I. 2. 2. 13.

There is another ophthalmia, which attends weak children, and is generally efteemed a symptom of scrosula, as described in Class II. 1. 5. 3. and another, which is of venereal origin, mentioned in Class II. 1. 5. 2. both which may be termed

ophthalmia fuperficialis.

3. Phrenitis. Inflammation of the brain is attended with intolerance of light and found; which shews, that the extremities of the nerves of those sense at the same time inflamed; it is also attended with great pain of the head, with watchfulness, and funious delirium. The violent efforts, these patients are said sometimes to exert, are owing to the increased secretion of sense rial power in the brain; as all other inflamed glands have a greater circulation of blood passing through them, and a greater secretion in consequence of their peculiar sluids, as in the hepatitis much more bile is generated.

M. M. Venefection. Cathartics. Torpentia. Foment the head with cold water for hours together. Or with warm water. Cool airy room. Afterwards cupping on the occiput. Leeches to the temples. When the patient is weakened a blifter on the head, and after further exhaultion five or fix drops of tincture

of opium.

4. Peripneumonia. Inflammation of the lungs. The pulse is not always hard, sometimes soft; which is probably owing to a degree of fickness or inaction of the stomach; with dull pain of the chest; respiration constantly difficult, sometimes with erect posture; the sace bloated and purplish; cough generally with moist expectoration, often stained with blood.

When the difficulty of respiration is very great, the patient is not able to cough; in this situation, after copious bleeding, the cough is liable to return, and is so far a favourable symptom, as it

thews fome abatement of the inflammation.

A peripneumony frequently occurs in the chin-cough, and destroys the patient, except immediate recourse be had to

the lancet, or to four or five leeches; when blood cannot be otherwise taken.

The peripneumony is very fatal to young children, especially as I believe it is frequently mistaken for a spasmodic asthma, or for the croup, or cynanche trachealis of Cullen. Both which, however, when they occur, require immediate venesection by the lancet or by leeches, as well as the peripneumony; as mentioned below.

Inflammation of the lungs is also liable to occur in the measles, and in the hooping-cough, and must be attacked by venesceion at any time of the disease; otherwise either a present death, or

an incurable confumption, is the confequence.

The peripneumony is frequently combined with inflammation of the pleura, and fometimes with that of the diaphragm; exher of these may generally be distinguished, not only by the pain which attends inflammation of these membranes, but by inspecting the naked chest, and observing whether the patient breathes more by elevating the ribs, or by depressing the diaphragm.

A crifis happens in children about the fixth day with much pale urine, which must be waited for after evacuations have been used, as far as can be done with safety; in this situation the warm bath twice a day, and small blifters repeatedly in succet-

fion, are of peculiar fervice.

After the termination of peripneumony a collection of coagulablelymph is frequently left in the cavity of the cheft unabforbed; or a common anafarca of the lungs occurs from the prefent inaction of the abforbent vessels, which had previously been excited too violently. This difficulty of breathing is cured or relieved by the exhibition of digitalis. See Art. IV. 2. 7.

M. M. The lancet is the anchor of hope in this disease; which must be repeated four or five times, or as often as the fever and difficulty of breathing increase, which is generally in the evening; antimonials, diluents, repeated fmall blifters about the chest, mucilage, pediluvium, warm bath. Is a decoction of seneca-root of use? Do not neutral salts increase the tendency to cough by their stimulus, as they increase the heat of urine in gonorrhœa? Children in every kind of difficult breathing, from whatever cause, should be kept as upright in bed as may be, and continually watched; fince, if they flip down, they are liable to be immediately fuffocated: to prevent which a pillow should be put beneath the undermost sheet half way down in the bed, so as to receive the posteriors of the child, and thus counteract its fliding down lower; or drawers on the thighs might be occasionally used for this purpose, as mentioned in Class III. 2. 1. 10. And children should have no cap string tied under

their chins, in any cough or difficulty of respiration, since if they slip down in their bed the friction of the night-cap on the pillow is liable to draw the tape or ribbon under the chin too tight, and sufficate them. After the patient is greatly debilitated, so that no further evacuation can be admitted, and the difficult breathing and cough continue, I have given four or five drops of tincture of opium, that is, about a quarter of a grain of solid opium, with great advantage, and I believe in several cases I have saved the patient. A greater quantity of opium in this state of debility cannot be used without hazarding the life of the person. This small quantity of an opiate should be given about six in the evening, or before the access of the evening paroxysm, and repeated three or four nights, or longer.

There is a peripneumony with weak pulse, which may be termed peripneumonia inirritata, as described in Sect. XXVII. 2. which belongs to this place. See also Superficial Peripneumo-

ny, Class II. 1. 3. 7.

Peripneumonia arthritica. Gouty peripneumony. I believe, that there exists a peripneumony, and a pleurify which owe their inflammation to the sympathy of those membranes with some other parts of the system, and may then properly be termed rheumatic or gouty peripneumony, or pleurify. And that the coagulable lymph left upon the inflamed membranes has generally been owing to these sympathetic inflammations, and that hydrops thoracis, and anasarca pulmonum are generally caused by gouty affections of the lungs, or rheumatic affections of the pleura, and not by the more common idiopathic inflammations of those membranes. See Class I. 2. 3. 14. and Class IV. 1. 2. 16. and Class IV. 1. 2.

Peripneumonia trachealis. Croup. The croup is an inflammation of the upper part, and the peripneumonia of the lower part of the fame organ, viz. the trachea or wind-pipe. See Class I. 1. 3. 4. But as the inflammation is feldom, I believe, confined to the upper part of the trachea only, but exists at the fame time in other parts of the lungs; and as no inflammation of the tonsils is generally perceptible, the uncouth name of cynanche trachealis should be changed for peripneumonia trachealis.

Dr. Wichmann, of Hanover, believes, that the acute afthma of Millar, or hives, has been confounded with the angina polypofa, or croup, which has occasioned the great difference in the treatment recommended by authors; as the difease has been esteemed inflammatory by some, and spasmodic by others.

The convultive afthma, which I have witnessed in one child, was readily diftinguished from the croup; as there was simply a great exertion in breathing, but without the harsh found which

attends

attends the inspirations in the latter, and there was no attendant fever; and the disease was cured by one venesection, and a moderate dose of opium after the venesection. See asthma convulsivum. Class III. 1. 10.

A convultive difficulty of respiration may thus be easily distinguished from the croup; as in the former the patient draws in the breath easily, and then voluntarily closes the larynx, and voluntarily uses great exertion in forcing out the breath, with design to relieve some pain by this violent exertion, as in parox-

yims of epileply.

On the contrary, in the croup the breath is easily expired, but the inspirations are attended with the utmost difficulty. This difficulty of inspiration may be seen by viewing the region of the stomach; as when the child raises the sternum for the purpose of drawing in its breath, the pressure of the atmosphere on the pit of the stomach presses the diaphragm upwards, and makes a sudden and great hollow in the scrobiculus cordis. This difficulty of inspiration, and not of expiration, is also known

by the harsh found, which only attends the inspiration.

This difficulty of inspiration may in part be owing to this circumstance. In diffecting those children who have died of the croup, I believe the upper part of the adherent coagulable lymph, or indurated mucus, formed within the trachea, is found to become loose, and to separate from the upper part of the trachea before the lower part of that adhesive membranous crust begins to separate, and hence the loose upper part at the time of inspiration is bent downwards into the trachea, and thus becomes double, and obstructs the passage; but this duplicature of it does not happen in expiration. See Transact. of a Society, Vol. II. Account of Croup, by Henry Ramsey, case the 8th. Might not this be prevented from being fatal, by an aperture into the wind-pipe beneath the larynx?

I have very lately feen a most distinct case of this peripneumonia trachealis, or croup. The child, about ten months old, had great difficulty in drawing in its breath, with much noise; but had much less difficulty in its expiration, with little or generally no found. On observing its naked cheft, the sternum, or breast-bone, was seen to be raised with great force; and then the diaphragm, and the bowels under it, rose hastily up into the lower part of the cavity of the cheft; and the air rushed with difficulty, and with great sound, through the contracted larynx into the upper part of the cheft; both these effects were evidently owing to the pressure of the atmosphere, to supply the vacuity, which must otherwise succeed the forcibly raising of the sternum.

Why the difficulty of inspiring was so much greater than Vol. II.

of expiring, requires to be further explained. During inspiration, the pressure of the atmosphere, when the cavity of the cheft is enlarged by raifing the fternum, and depressing the diaphragm, acts upon the external part of the larynx, as well as on the aperture of it, and thus contracts it, and affifts the difease; whereas in expiration there is no increase of atmospheric preffure on the outfide of the larvnx, or trachea, to prevent the exclusion of the air. In the fame manner, if a flexible pipe of foft leather was extended upwards a few inches through the bottom of a bucket of water, but very little of the water could be difcharged by it; as the pressure on its sides would soon compress the pipe, and thus stop up its mouth.

After repeated venefection, and a cathartic of calomel, a blifter was applied on each fide of the larynx, and the difficulty of breathing became greatly relieved; and though the child had intervals of easier respiration, and without noise, yet it died on the

fucceeding day.

Where the difficulty of breathing is very urgent in the croup, bronchotomy is recommended by Mr. Field. Memoirs of a

Medical Society, London, 1773, Vol. IV.

After repeated venefection, and cathartics, perhaps a drop or two drops of tincture of opium, about fix in the evening, might be of use to prevent the return of the evening paroxysm, and this especially if the difficulty of respiration has an interval or remis-

fion, as mentioned below.

A strong decoction of seneca root is recommended by Dr. Archer, of America. He boils half an ounce of the root, from eight ounces of water to four, and gives a tea-spoonful every hour or half hour, fo as to produce vomiting or purging, and then gives it in smaller quantities. He also rubs mercurial ointment about the throat, and uses calomel internally, so as to affect the glands of the throat as quickly as possible, when the difease is more advanced, and the difficulty of breathing with harsh and shrill inspiration is more urgent. Medical and Physical Journal, No. I. p. 83. As a decoction of feneca root particulary stimulates some parts of the throat, occasioning a disagreeable fensation in it, it may in some cases contribute to loosen or discharge the adhesive coagulable lymph, which has been secreted on the inflamed membrane of the wind-pipe, and occasions the difficulty of infpiration by contracting its aperture; and may therefore be worth trial after repeated venefection, and cathartics, and blifters on each fide of the throat.

Dr. Wichmann of Hanover, above mentioned, afferts, that in the croup the difease continues regularly to increase, from the commencement of it, without intervals of relief from the great

difficulty

difficulty of breathing; and gives this as a criterion to distinguish the angina polyposa from the asthma acutum. Annals of Medicine, Vol. I. But in the cases of true croup, peripneumonia trachealis, I have seen with surprise the difficulty of respiration to cease for a time, and return again with unabated violence. These remissions of the dissipult respiration are also mentioned by Dr. Ferriar, who then terms it a spurious croup, but which I suspect to be owing simply to the following circumstances.

In a common catarrh, when the mucous membrane of the nostrils is much inflamed, it becomes so thickened as totally to prevent respiration through them; yet on suddenly warming the skin, by drinking tea or by a sire, and sometimes by only cooling the membrane of the nostrils by going into the cold air, the swelling of this membrane will suddenly subside, so as to permit the air to pass through quite easily for a time, as explained in catarrhus calidus. Class I. 1. 2. 7. The same circumstance may occur to the inflammation of the membrane, which lines the upper part of the trachea, or it may happen from the doubling of

the loofened upper part of the adhelive mucus.

M. M. Frequent bleeding by the lancet or leeches. A few grains of calomel. Seneca. Blifters about the throat. An opiate in small quantity at night after previous evacuations. Mercurial ointment. Warm bath. Breathing over the steam of warm water, with or without volatile alkali, or ether, or vinegar. Particular attention should be used to keep the child raised high in bed. Might the skin be kept agreeably warm, and at the same time might quite cold air be breathed through a tube coming from without, through a broken window, or hole in a door? Or might the child be carried out into the cold air very warmly clad? If a solution of sublimate could be safely used, as in gonorrhæa, Class II. 1. 5. 1?

After evacuation by copious venefaction, might not the frequent application of other externally to the throat be ferviceable? And where there occur intervals of eafy refpiration, might not breathing over the dust of powdered Peruvian bark prevent a return of the thickening of the membrane, as described in Class II.

1. 6. 7.

5. Pleuritis. Pleurify. Inflammation of the pleura, with hard pulse, pain chiefly of the side, pungent, particularly increased during inspiration; lying on either side uneasy, the cough very painful, dry at the beginning, afterwards moist, often bloody.

One cause of pleurify is probably a previous adhesion of the lungs to a part of the pleura, which envelopes them. This in many cases has been produced in infancy, by suffering children to lie too long on one side. Or by placing them uniformly on one

fide of a fire, or window, to which they will be liable always to bend themselves.

When matter is produced during peripneumony or pleurify in one fide of the cheft, so long as it is a concealed vomica, the fever continues, if the disease be great, for many weeks, and even months; and requires occasional venesection, till the patient finks under the inflammatory or sensitive irritated sever. But if air be admitted, by a part of the abscess opening itself a way into the air-vessels of the lungs, a hectic sever, with colliquative sweats or diarrhæa, supervenes, and frequently destroys the patient; or the abscess heals, the lungs adhering to the pleura. See pleurodyne rheumatica. Class IV. 1. 2. 16.

M. M. The lancet must be used copiously, and repeated as often as the pain and difficult respiration increase. A blister on the pained part. Antimonial preparations. Diluents. Cool air. Do neutral salts increase the tendency to cough? Pedi-

luvium or femicupium frequently repeated.

6. Diaphragmitis. Inflammation of the diaphragm. Pain round the lower ribs as if girt with a cord. Difficult respiration performed only by elevating the ribs and in an erect posture. The corners of the mouth frequently retracted into a dis-

agreeable fmile, called rifus Sardonicus.

Those animals, which are furnished with clavicles, or collarbones, not only use their foremost feet as hands, as men, monkeys, cats, mice, fquirrels, &c. but elevate their ribs in respiration as well as depress the diaphragm for the purpose of enlarging the cavity of the cheft. Hence an inflammation of the diaphragm is fudden death to those animals, as horses and dogs, which can only breathe by depressing the diaphragm; and is I suppose the cause of the sudden death of horses that are overworked; whereas, in the human animal, when the diaphragm is inflamed, so as to render its motions impossible from the pain they occasion, respiration can be carried on, though in a less perfect manner, by the intercostal muscles in the elevation of the ribs. In pleurify the ribs are kept motionless, and the respiration is performed by the diaphragm, as may be readily feen on inspecting the naked cheft, and which is generally a bad symptom; in the diaphragmitis the ribs are alternately elevated, and depressed, but the lower part of the belly is not seen to move.

M. M. As in pleurify and peripneumony. When the patient becomes delirious, and fimiles difagreeably by intervals, and is become fo weak, that evacuations by the lancet could be used no further, and I have almost despaired of my patient, I have found in two or three instances, that about five or fix drops of tinct. thebaic. given an hour before the evening exacerbation,

have had the happiest effect, and cured the patient in this case, as well as in common peripneumony; it must be repeated two or three evenings, see Class II. 1. 2. 4. as the exacerbation of the fever, and difficult respiration, and delirium, generally in-

crease towards night.

The stimulus of this small quantity of opium on a patient previously so much debilitated, acts by increasing the exertion of the absorbent vessels, in the same manner as a solution of opium, or any other stimulant, put on an inflamed eye after the vessels are previously emptied by evacuations, stimulates the absorbent fystem, so as to cause the remaining new vessels to be immediately reabforbed. Which fame stimulants would have increased the inflammation, if they had been applied before the evacuations. See Class II. 1. 2. 2. Sect. XXXIII. 2. 1. When the fanguiferous fystem is full of blood, the absorbents cannot act so powerfully, as the progress of their contents is opposed by the previous fulness of the blood-vessels; whence stimulants in that case increase the action of the secerning system more than of the absorbent one; but after copious evacuation this refistance to the progress of the absorbed fluids is removed; and when stimulants are then applied, they increase the action of the absorbent system more than that of the secerning one. Hence opium given in the commencement of inflammatory diseases destroys the patient; and cures them, if given in very small doses at the end of inflammatory diseases.

7. Carditis. Inflammation of the heart is attended with unequal intermitting pulse, palpitation, pain in the middle of the sternum, and constant vomiting. It cannot certainly be distinguished from peripneumony, and is perhaps always combined

with it.

8. Peritonitis. Inflammation of the peritonæum is known by pain all over the abdomen, which is increased on erecting the body. It has probably most frequently a rheumatic origin. See

Class II. 1. 2. 17.

9. Mesenteritis. Inflammation of the mesentery is attended with pains like colic, and with curdled or chyle-like stools. It is a very frequent and dangerous disease, as the production of matter more readily takes place in it than in any other viscus. The consequence of which, after a hard labour, is probably the puerperal sever, and in scrosulous habits a satal purulent sever, or hopeless consumption.

M. M. Venesection. Warm bath. Emollient clysters.

10. Gastritis. In inflammation of the stomach the pulse is generally soft, probably occasioned by the sickness which attends

it. The pain and heat of the stomach are increased by whatever is swallowed, with immediate rejection of it. Hiccough.

This difease may be occasioned by acrid or indigestible matters taken into the stomach, which may chemically or mechanically injure its interior coat. There is however a slighter species of inflammation of this viscus, and perhaps of all others, which is unattended by much sever; and which is sometimes induced by drinking cold water, or eating cold insipid food, as raw turnips, when the person has been much heated and satigued by exercise. For when the sensorial power has been diminished by great exertion, and the stomach has become less irritable by having been previously stimulated by much heat, it sooner becomes quiescent by the application of cold. In consequence of this slight inflammation of the stomach an eruption of the face frequently ensues by the sensitive association of this viscus with the skin, which is called a surfeit. See Class IV. 1. 2. 13. and II. 1. 4. 6. and II.

M. M. Venesection. Warm bath. Blifter. Anodyne clys-

ters. Almond foap. See Class II. 1. 3. 17.

11. Enteritis. Inflammation of the bowels is often attended with foft pulse, probably owing to the concomitant fickness; which prevents fometimes the early use of the lancet, to the destruction of the patient. At other times it is attended with strong and full pulse like other inflammations of internal membranes. Can the feat of the difease being higher or lower in the intestinal canal, that is, above or below the valve of the co-Ion, produce this difference of pulse by the greater sympathy of one part of the bowels with the stomach than another? In enteritis with strong pulse the pain is great about the navel, with vomiting, and the greatest difficulty in procuring a stool. In the other, the pain and fever are lefs, without vomiting, and with diarrhoea. Whence it appears, that the enteritis with hard quick pulse differs from ileus, described in Class I. 3. 1. 6. only in the existence of fever in the former and not in the latter, the other fymptoms generally corresponding; and, secondly, that the enteritis with fofter quick pulse, differs from the cholera defcribed in Class I. 3. 1. 5. only in the existence of fever in the former, and not in the latter, the other fymptoms being in general fimilar. See Class II. 1. 3. 20.

Inflammation of the bowels fometimes is owing to extraneous indigestible substances, as plum-stones, especially of the dama-fin, which has sharp ends. Sometimes to an introsusception of one part of the intestine into another, and very frequently to a strangulated hernia or rupture. In respect to the first, I knew an instance where a damasin stone, after a long period of time,

found

found its way out of the body near the groin. I knew another child, who vomited fome damasin stones, which had lain for near twenty hours, and given great pain about the navel, by the exhibition of an emetic given in repeated doses for about an hour. The swallowing of plum-stones in large quantities, and even of cherry-stones, is annually satal to many children. In respect to the introsusception and hernia, see Ileus, Class I. 3. 1. 6.

M. M. Repeated venefection. Calomel from ten to twenty grains given in small pills as in ileus; these means used early in the disease generally succeed. After these evacuations a blister contributes to stop the vomiting. Warm bath. Crude mercury. Aloes one grain-pill every hour will frequently stay in the stomach. Glauber's salt dissolved in pepper-mint water given by

repeated spoonfuls.

When the patient is much reduced, opium in very small dofes may be given, as a quarter of a grain, as recommended in pleurify. If the pain suddenly ceases, and the patient continues to vomit up whatever is given him, it is generally statl; as it indicates, that a mortification of the bowel is already formed. Some authors have advised to join cathartic medicines with an opiate in inflammation of the bowels, as recommended in colica saturnina. This may succeed in slighter cases, but is a dangerous practice in general; since, if the obstruction be not removed by the evacuation, the stimulus of the opium is liable to increase the action of the vessels, and produce mortification of the bowel, as I think I have seen more than once. Mercury injected by the anus, or water by a forcing-pump. See Ileus I. 3. 1. 6.

12. Hepatitis. Inflammation of the liver is attended with fitrong quick pulse; tension and pain of the right side; often pungent as in pleurify, oftener dull. A pain is said to affect the clavicle, and top of the right shoulder; with disficulty in lying on the left side; difficult respiration; dry cough; vomiting;

hiccough.

There is another hepatitis mentioned by authors, in which the fever, and other fymptoms, are wanting, or are lefs violent; as defcribed in Class II. 1. 4. 11. and which is probably fometimes relieved by eruptions of the face; as in those who are ha-

bituated to the intemperate use of fermented liquors.

M. M. Hepatic inflammation is very liable to terminate in fuppuration, and the patient is destroyed by the continuance of a fever with fizy blood, but without night sweats, or diarrheea, as in other unopened abscesses. Whence copious and repeated venesection is required early in the disease, with repeated doses of calomel, and cathartics. Warm bath. Towards the end of the disease small doses of opium before the evening paroxysms,

and

and lastly the Peruvian bark, and chalybeate wine, at first in small doses, as 20 drops twice a day, and afterwards, if necessary

ry, in larger. See Art. IV. 2. 6.

Towards the end of hepatitis, after repeated venefection and catharfis, an eruption fometimes appears round the lips, which is generally a falutary fymptom: and the decoction of Peruvian bark given at this time, in the quantity of about two ounces every fix hours, removes the remaining inflammatory tendency, and cures in a day or two.

Mrs. C. a lady in the last month of her pregnancy, was seized with violent hepatitic, with symptoms both of peripneumony and of pleurify, for it seldom happens in violent inflammations, that one viscus alone is affected; she wanted then about a fortnight of her delivery, and after frequent venesection, with gentle cathartics, with somentation or warm bath, she recovered and was safely delivered, and both herself and child did well. Rheumatic and eruptive severs are more liable to induce abortion.

13. Splenitis. Inflammation of the spleen commences with tension, heat, and tumour of the left side, and with pain, which is icreased by pressure. A case is described in Class I. 2. 3. 18. where a tumid spleen, attended with sever, terminated in scir-

rhus of that vifcus.

14. Nephritis. Inflammation of the kidney feems to be of two kinds; each of them attended with different fymptoms, and different modes of termination. One of them I suppose to be an inflammation of the external membrane of the kidney, arifing from general causes of inflammation, and accompanied with pain in the loins without vomiting; and the other to confist in an inflammation of the interior parts of the kidney, occasioned by the stimulus of gravel in the pelvis of it, which is attended with perpetual vomiting, with pain along the course of the ureter, and retraction of the testis on that side, or numbres of the thigh.

The former of these kinds of nephritis is distinguished from lumbago by its situation being more exactly on the region of the kidney, and by its not being extended beyond that part; after three or four days I believe this inflammation is liable to change place; and that a herpes or erysipelas, called zona, or shingles, breaks out about the loins in its stead; at other times it is cured by a cathartic with calomel, with or without previous venesec-

tion.

The other kind of nephritis, or inflammation of the interior part of the kidney, generally arises from the pain occasioned by the stimulus of a stone entering the ureter from the pelvis of the kidney; and which ceases when the stone is protruded forwards into the bladder; or when it is returned into the pelvis of the kidney

kidney by the retrograde action of the ureter. The kidney is nevertheles inflamed more frequently, though in a less degree, from other causes; especially from the intemperate ingurgitation of ale, or other fermented or spirituous liquors. This less degree of inflammation is the cause of gravel, as that before mentioned is the effect of it. The mucus secreted to lubricate the internal surface of the uriniferous tubes of the kidney becomes secreted in greater quantity, when these vessels are inflamed; and, as the correspondent absorbent vessels act more energetically at the same time, the absorption of its more fluid parts is more powerfully affected; on both these accounts the mucus becomes both changed in quality and more indurated. And in this manner stones are produced on almost every mucous membrane of the body; as in the lungs, bowels, and even in the pericardium, as some writers have affirmed. See Class I. 1. 2. 0.

M. M. Venefection. Ten grains of calomel given in small pills, then insusion of sena with oil. Warm bath. Then opium a grain and half. See Class I. 1. 3. 9. for a further ac-

count of the method of cure.

15. Cyfitis. Inflammation of the bladder is attended with tumor and pain of the lower part of the belly; with difficult and painful micturition; and tenefimus. It generally is produced by the existence of a large stone in the bladder, when in a great degree; or is produced by common causes, when in a

flighter degree.

The stone in the bladder is generally formed in the kidney. and passing down the ureter into the bladder becomes there gradually increased in fize; and this most frequently by the apposition of concentric spheres, as may be seen by fawing some of the harder calculi through the middle, and polishing one furface. These new concretions superinduced on the nucleus, which descended from the kidney, as described in Class I. 1. 3. 9. and in the preceding article of this genus, is not owing to the microcosmic salt, which is often seen to adhere to the sides of chamber-pots, as this is foluble in warm water, but to the mucus of the bladder, as it rolls along the internal furface of it. Now when the bladder is flightly inflamed, this mucus of its internal furface is fecreted in greater quantity, and is more indurated by the absorption of its more liquid part at the instant of secretion, as explained in Class I. 1. 3. 9. and II. 1. 2. 14. and thus the stimulus and pain of a stone in the bladder contribute to its enlargement by inflaming the interior coat of it.

M. M. Venesection. Warm bath. Diluents. Anodyne

clysters. See Class I. 1. 3. 9.

16. Hysteritis. Inflammation of the womb is accompanied Vol. II.

with heat, tension, tumour, and pain of the lower belly. The os uteri painful to the touch. Vomiting. This disease is generally produced by improper management in the delivery of pregnant women. I knew an unfortunate case, where the placenta was left till the next day; and then an unskilful accoucheur introduced his hand, and forcibly tore it away; the consequence was a most violent inflammatory sever, with hard throbbing pulse, great pain, very sizy blood, and the death of the patient. Some accoucheurs have had a practice of introducing their hand into the uterus immediately after the birth of the child, to take away the placenta; which they said was to save time. Many women I believe have been victims to this unnatural practice.

Others have received injury, where inflammation has been beginning, by the universal practice of giving a large dose of opium immediately on delivery, without any indication of its propriety; which, though a proper and useful medicine, where the patient is too feeble, when given in a small dose, as to drops of tincture of opium, or half a grain of folid opium, must do a proportionate injury, when it is given improperly; and as delivery is a natural process, it is certainly more wise to give no medicines, except there be fome morbid fymptom, which requires it; and which has only been introduced into custom by the ill-employed activity of the priests or priestesses of Lucina; like the concomitant nonfense of cramming rue or rhubarb into the mouth of the unfortunate young stranger, who is thus foon made to experience the evils of life. See Class II. 1. 1. 12. and I. 1. 2. 5. Just so some over-wife beldames force young ducks and turkeys, as foon as they are hatched, to fwallow a pepper corn.

M. M. Venefection repeatedly; diluents; fomentation; the patient should be frequently raised up in bed for a short time, to give opportunity of discharge to the putrid lochia; mucilag-

inous clysters. See Febris Puerpera.

17. Lumbago fensitiva. Sensitive lumbago. When the extensive membranes, or ligaments, which cover the muscles of the back are torpid, as in the cold paroxysm of ague, they are attended with pain in consequence of the inaction of the vessels, which compose them. When this inaction continues without a consequent renewal or increase of activity, the disease becomes chronical, and forms the lumbago frigida, or irritativa described in Class I. 2. 4. 16. But when this cold fit or torpor of these membranes, or ligaments or muscles of the back, is succeeded by a hot fit, and consequent inflammation, a violent inflammatory fever, with great pain, occurs, preventing the erect posture of

the body, and the affected part is liable to suppurate, in which case a very dangerous ulcer is formed, and a part of one of the vertebræ is generally found carious, and the patient sinks after a long time under the hectic sever occasioned by the aerated or

oxygenated matter,

This difease bears no greater analogy to rheumatism than the inflammation of the pleura, or any other membranous inflammation; and has therefore unjustly been arranged under that name. It is distinguished from nephritis, as it is seldom attended with vomiting, I suppose never, except the ureter happens to be inflamed at the same time.

The pain fometimes extends on the outfide of the thigh from the hip to the ankle, heel, or toes, and is then called sciatica; and has been thought to confist in an inflammation of the theca, or covering of the sciatic nerve, as the pain sometimes so exactly attends the principal branches of that nerve. See Class

I. 2. 4. 15. 16.

M. M. Venesection repeatedly; calomel; gentle cathartics; diluents; warm bath; poultice on the back, consisting of camomile flowers, turpentine, soap, and opium; a burgundy-pitch plaster. A debility of the inferior limbs from the torpor of the muscles, which had previously been too much excited, frequently occurs at the end of this disease; in this case electricity, and issues on each side of the lumbar vertebræ, are recommended. See Class I. 2. 4. 16.

18. Ifchias. The ischias consists of inflammatory fever, with great pain about the pelvis, the os coccygis, and the heads of the thigh-bones, preventing the patient from walking or standing erect, with increase of pain on going to stool. This malady, as well as the preceding, has been ascribed to rheumatism; with which it seems to bear no greater analogy, than the inflamma-

tions of any other membranes.

The patients are left feeble, and fometimes lame after this difease; which is also fometimes accompanied with great flow of urine, owing to the defective absorption of its aqueous parts; and with consequent thirst occasioned by the want of so much fluid being returned into the circulation; a lodgment of fæces in the rectum sometimes occurs after this complaint from the lessened sensibility of it. See Class I. 2. 4. 15.

M. M. Venefection; gentle cathartics; diluents; fomentation; poultice with camomile flowers, turpentine, foap, and

opium; afterwards the bark. See Class I. 1. 3. 5.

When this inflammation terminates in suppuration the matter generally can be felt to sluctuate in the groin, or near the top of the thigh. In this circumstance, my friend Mr. Bent, surgeon, near Newcastle in Staffordshire, proposes to tap the abscess by means of a trocar, and thus as often as necessary to discharge the matter without admitting the air. Might a weak injection of wine and water, as in the hydrocele, be used with great caution to inslame the walls of the abscess, and cause them to unite? See Class II. 1.6.9.

The pain occasioned by the inflammatory action and tumor of parts bound down between the nail on one side and the bone on the other, neither of which will yield, is said to occasion so much pain as to produce immediate delirium, and even death, except the parts are divided by a deep incision; which must pass quite through the periosteum, as the inflammation is said generally to exist beneath it. This disease is thus resembled by the process of toothing in young children; where an extraneous body lodged beneath the periosteum induces pain and sever, and sometimes delirium, and requires to be set at liberty by the lancet.

ORDO I.

Increased Sensation.

GENUS III.

With the Production of new Veffels by external Membranes or Glands, with Fever.

THE diseases of this genus are perhaps all productive of contagious matter; or which becomes so by its exposure to the air, either through the cuticle, or by immediate contact with it; fuch are the matters of the small-pox and measles. The purulent matter formed on parts covered from the air by thicker membranes or muscles, as in the preceding genus, does not induce fever; and cannot therefore be called contagious; but it acquires this property of producing fever in a few hours, after the abscess has been opened, so as to admit the air to its surface, and may then be faid to confift of contagious miasmata. kind of contagious matter only induces fever, but does not produce other matter with properties similar to its own; and in this respect it differs from the contagious miasmata of small-pox or measles, but resembles those which have their origin in crowded jails; for these produce fever only, which frequently destroys the patient; but do not produce other matters similar to themselves; as appears from none of those who died of the jailfever, caught at the famous black affizes at Oxford, at the beginning of this century, having infected their physicians or attendants.

If indeed the matter has continued so long as to become putrid, and thus to have given out air from a part of it, it acquires the power of producing sever; in the same manner as if the ulcer had been opened, and exposed to the common air; instances of which are not unfrequent. And from these circumstances it seems probable, that the matters secreted by the new vessels formed in all kinds of phlegmons, or pustules, are not contagious, till they have acquired something from the atmosphere, or from the gas produced by putresaction; which will account for some phenomena in the lues venerea, cancer, and of other contagious secretions on the skin without sever, to be mentioned hereafter. See Class II. 1. 4. 14.

The theory of contagion has been perplexed by comparing it with fermenting liquors; but the contagious material is shewn in Section XXXIII. to be produced like other secreted matters

by certain animal motions of the terminations of the veffels. Hence a new kind of gland is formed at the terminations of the veffels in the eruptions of the small-pox; the animal motions of which produce from the blood variolous matter; as other glands produce bile or faliva. Now if some of this matter is introduced beneath the cuticle of a healthy person, or enters the circulation, and excites the extremities of the blood-vessels into those kinds of difeafed motions, by which it was itfelf produced, either by irritation or affociation, these diseased motions of the extremities of the veffels will produce other fimilar contagious matter. See Sect. XXXIII. 2. 5. and 9. Hence contagion feems to be propagated two ways; one, by the stimulus of contagious matter applied to the part, which by an unknown law of nature excites the stimulated vessels to produce a similar matter; as in venereal ulcers, which thus continue to foread; or as when variolous matter is inferted beneath the cuticle; or when it is supposed to be absorbed, and diffused over the body mixed with the blood, and applied in that manner to the cutaneous glands. The other way, by which contagion feems to be diffused, is by some distant parts sympathizing or imitating the motions of the part first affected; as the stomach and skin in the eruptions of the inoculated fmall-pox, or in the bite of a mad dog; as treated of in Sect. XXII. 3. 3.

In some of the diseases of this genus, the pulse is strong, full, and hard, constituting the sensitive irritated sever, as described in the preceding genus; as in one kind of erysipelas, which requires repeated venesection. In others the arterial action is sometimes moderate, so as to constitute the sensitive sever, as in the inoculated small-pox; where the action of the arteries is neither increased by the sensorial power of irritation, as in the sensitive irritated sever; nor decreased by the defect of that power, as in the sensitive inirritated sever. But in the greatest number of the diseases of this genus the arterial action is greatly diminished in respect to strength, and consequently the frequency of pulsation is proportionally increased, as explained in Sect. XXXII. 2. 1. Which is owing to the desciency of the sensorial power of irritation joined with the increase of that of sensorial power of irritation joined with the increase of that of sensorial power of irritation is proportionally increased of that of sensorial power of irritation joined with the increase of that of sensorial power of irritation is proportionally increased of that of sensorial power of irritation joined with the increase of that of sensorial power of irritation is proportionally increased of that of sensorial power of irritation joined with the increase of that of sensorial power of irritation is proportionally increased in sensorial power of irritation joined with the increase of that of sensorial power of irritation joined with the increase of that of sensorial power of irritation joined with the increase of that of sensorial power of irritation is proportionally increased as a sensorial power of irritation is proportionally increased in Sect.

fcarlatina with gangrenous tonfils.

From this great debility of the action of the arteries, there appears to be lefs of the coagulable lymph or mucus fecreted on their internal furfaces; whence there is not only a defect of that buff or fize upon the blood, which is feen on the furface of that which is drawn in the fenfitive irritated fever; but the blood, as it cools, when it has been drawn into a bafin, fearcely

coagulates; and is faid to be diffolved, and is by some supposed to be in a state of actual putrefaction. See Sect. XXXIII. 1.
3. where the truth of this idea is controverted. But in the severs of both this genus and the preceding one, great heat is produced from the chemical combinations in the secretions of new vessels and sluids, and pain or uneasiness from the distention of the old ones; till towards the termination of the disease sense. The affected parts, and the death of the patient.

Dyfenteria, as well as tonfillitis and aphtha, are enumerated amongst the diseases of external membranes, because they are exposed either to the atmospheric air, which is breathed and swallowed with our food and saliva; or they are exposed to the inflammable air, or hydrogen, which is generated in the intestines; both which contribute to produce or promote the contagious quality of these sluids; as mentioned in Class II. 1. 6.

It is not speaking accurate language, if we say, that, in the diseases of this genus the sever is contagious; since it is the material produced by the external membranes which is contagious, after it has been exposed to air; while the sever is the consequence of this contagious matter, and not the cause of it. As appears from the inoculated small-pox, in which the sever does not commence, till after suppuration has taken place in the inoculated arm, and from the diseases of the sifth genus of this order, where contagion exists without sever. See Class II. 1. 5. and II. 1. 3. 18.

The existence of contagious miasmata in the atmosphere was believed even in the time of Homer, and was allegorized under the title of the arrows of Apollo. See catarrhus contagious, II. 1. 3. 6. Of these it is probable, that some contagious matters are only diffused in the atmosphere, as that of the smallpox, as it seems only to infect those who are very near the variolous patient; and seems to be swallowed with the saliva, and thence to affect the tonsils. Other contagions may be dissolved in the atmosphere, as that of the measles, and of epidemic catarrhs, which therefore first affect the membranes of the nostrils in men, and of the maxillary sinuses also in dogs and horses.

Contagious materials have been also believed from remote antiquity to lodge in the walls of rooms where the sick have been confined; as in the wards of hospitals, jails, ships, as well as in the bedding or clothes of the infected. The methods of purifying infected houses seem also to have been studied in the remote times; the Levitical law directs the walls of the house of a leprous person to be scraped; and in modern times white-

washings

washings with lime and painting with oil have been directed, I

believe with great fuccess.

Mr. Cruickshank has lately recommended two or three parts of sulphur with one of nitre to be mixed together, and set in a room close shut up, and ignited by dropping a lighted coal upon it; as the nitre will supply sufficient oxygen to inslame the sulphur in a close apartment, and thus to sill the whole with the sulphurous vapour; so as to pass into every minute aperture of the walls or furniture.

Another means of fweetening the air of hospitals, where many ulcerous patients are crowded together, has been also recommended, and might perhaps be used with falutary effect to restore the air of play-houses, churches, close parlours, courts of law, and other places, where many people resort without due ventilation, which consists in well mixing four ounces of common falt with two ounces of pulverized manganese in a basin, to these are then to be added about two ounces of water, and afterwards three ounces of concentrated sulphuric acid, in small portions at a time; and when managed in this way the gas is faid not to be in the least offensive itself, and at the same time destroys disagreeable smells, and perhaps also insectious miasmata. Medical Review, No. 32.

The white vapours, not the red ones, of nitrous acid have been employed with wonderful fuccefs, by Dr. C. Smyth, in the hofpital ships, without removing the patients; some fand is made hot in crucibles, many of which are brought into the rooms to be sumigated; in this hot sand is then set a tea-cup containing about half an ounce of concentrated vitriolic acid, to which, after it had acquired a proper heat, an equal quantity of nitre in powder is gradually added, and the mixture stirred with a glass spatula, till the vapour arises from it in considerable quantity. The crucible or pipkin is then carried about the wards by the nurses or convalescents, who walk about with them, like incense-pots, in their hands, and by thus sumigating the ship morning and night, with the care of washing the beds and clothes, and exposing them to the air, the contagion appeared to be quickly stopped, and the patients already affected soon recovered.

If any metalic vessel be used, the white nitrous vapour becomes red, and what was falutary before becomes now noxious, as is observed by Mr. Keir, in his letter on this subject, who adds, that though much vital air is extricated from the mixture, he rather ascribes its good effect to the known property of all mineral acids in stopping the processes of fermentation and putresaction; as the contagious miassmata are presumed to consist

of animal matter in some vicious kind of fermentation. Medical Review, Vol. III. p. 17.

SPECIES.

1. Febris fensitiva inirritata. Sensitive inirritated fever. Typhus gravior. Putrid malignant fever. Jail fever. The immediate cause of this disease is the increase of the sensorial power of sensation, joined with the decrease of the sensorial power of irritation; that is, it consists in the febris sensitiva joined with the febris inirritativa of Class I. 2. 1. 1. as the sebris sensitiva irritata of the preceding genus consists of the febris sensitiva joined with the febris irritativa of Class I. 1. 1. 1. In both which the words irritata, and inirritata, are designed to express more or less irritation than the natural quantity; and the same when

applied to some of the diseases of this genus.

This fever is frequently accompanied with topical inflammation, which is liable, if the arterial strength is not supported, to end in sphacelus; and as mortified parts, such as sloughs of the throat, if they adhere to living parts, soon become putrid from the warmth and moisture of their situation; these fevers have been termed putrid, and have been thought to owe their cause to what is only their consequence. In hot climates this sever is frequently induced by the exhalations of stagnating lakes or marshes, which abound with animal substances; but which in colder countries produce severs with debility only, as the quar-

tan ague, without inflammation.

The fensitive inirritated, or malignant, fever is also frequently produced by the putrid exhalations and stagnant air in prisons; but perhaps most frequently by contact or near approach of the persons who have resided in them. These causes of malignant severs contributed to produce, and to support for a while, the septic and antiseptic theory of them; see Sect. XXXIII. 1. 3. The vibices or bruises, and petechiæ or purples, were believed to be owing to the dissolved state of the blood by its incipient putresaction; but hydrostatical experiments have been made, which shew the fizy blood of the patient in sensitive irritated or inflammatory fever, with strong pulse, is more sluid, while it is warm, than this uneoagulable blood taken in this sensitive inirritated, or malignant sever; from whence it is inferred, that these petechiæ, and vibices, are owing to the desicient power of absorption in the terminations of the veins. See Class I. 2. 1. 5.

This fensitive inirritated fever, or typhus gravior, is distinguished from the inirritative fever, or typhus mitior, in the early stages of it, by the colour of the skin; which in the latter is Vol. H.

paler, with less heat, owing to the less violent action of the capillaries; in this it is higher coloured, and hotter, from the greater energy of the capillary action in the production of new veffels. In the more advanced state petechiæ, and the production of contagious matter from inflamed membranes, as the aphthæ of the mouth, or ulcers of the throat, distinguish this fever from the former. Delirium, and dilated pupils of the eyes, are more frequent in nervous fevers; and stupor with deafness a more frequent attendant on malignant fevers. See Class I. 2. 5. 6.

There is another criterion discernible by the touch of an experienced finger; and that is, the coat of the artery in inflammatory fevers, both those attended with strength of pulsation, and these with weak pulsation, feels harder, or more like a cord; for the coats of the arteries in these fevers are themselves inflamed and are consequently turgid with blood, and thence are less easily compressed, though their pulsations are nevertheless weak; when the artery is large or full with an inflamed coat, it is called hard; and when small or empty with an inflamed coat, it is called sharp, by many writers.

M. M. The indications of cure confift, 1. In procuring a regurgitation of any offensive material, which may be lodged in the long mouths of the lacteals or lymphatics, or in their tumid glands. 2. To excite the fystem into necessary action by the repeated exhibition of nutrientia, forbentia, and incitantia; and to preserve the due evacuation of the bowels. 3. To prevent any unnecessary expenditure of sensorial power. 4. To prevent the formation of ulcers, or to promote the absorption in them,

for the purpose of healing them.

1. One ounce of wine of ipecacuanha, or about ten grains of the powder, should be given as an emetic. After a few hours three or four grains of calomel should be given in a little mucilage, or conserve. Where something swallowed into the stomach is the cause of the sever, it is liable to be arrested by the lymphatic glands, as the matter of the small-pox inoculated in the arm is liable to be stopped by the axillary lymphatic gland; in this situation it may continue a day or two, or longer, and may be regurgitated during the operation of an emetic or cathartic into the stomach or bowel, as evidently happens on the exhibition of calomel, as explained in Sect. XXIX. 7. 2. For this reason an emetic and cathartic, with venesection, if indicated by the hardness and sulness of the pulse, will very frequently remove fevers, if exhibited on the first, second, or even third day.

2. Wine and opium, in small doses repeated frequently, but so that not the least degree of intoxication sollows, for in that case a greater degree of debility is produced from the expendi-

ture of fenforial power in unnecessary motions. Many weak patients have been thus stimulated to death. See Sect. XII. 7. 8. The Peruvian bark should be given also in repeated doses in fuch quantity only as may strengthen digestion, not impede it. For these purposes two ounces of wine, or of ale, or cyder, should be given every fix hours; and two ounces of decoction of bark, with two drachms of the tincture of bark, and fix drops of tincture of opium, should be given also every fix hours alternately; that is, each of them four times in twenty-four hours. As much rhubarb as may induce a daily evacuation, should be given to remove the colluvies of indigested materials from the bowels; which might otherwise increase the distress of the patient by the air it gives out in putrefaction, or by producing a diarrhœa by its acrimony; the putridity of the evacuations is owing to the total inability of the digestive powers; and their delay in the intestines, to the inactivity of that canal in respect to its peristaltic motions.

The quantities of wine or beer and opium, and bark, abovementioned, may be increased by degrees, if the patient seems refreshed by them; and if the pulse becomes slower on their exhibition; but this with caution, as I have seen irrecoverable mischief done by greater quantities both of opium, wine, and bark, in this kind of sever; in which their use is to strengthen the digestion of the weak patient, rather than to stop the paroxysms of sever; but when they are administered in intermit-

tents, much larger quantities are necessary.

The stimulus of small blisters applied in succession, one every three or four days, when the patient becomes weak, is of great fervice by strengthening digestion, and by preventing the coldness of the extremities, owing to the sympathy of the skin with

the stomach, and of one part of the skin with another.

In respect to nutriment, the patient should be supplied with wine and water, with toasted bread, and sugar or spice in it; or with sago with wine; fresh broth with turnips, cellery, parsley, fruit; new milk. Tea with cream and sugar; bread-pudding, with lemon-juice and sugar; chicken, fish, or whatever is grateful to the palate of the sick person, in small quantity repeated frequently; with small beer, cyder and water, or wine and water, for drink, which may be acidulated with acid of vitriol in small quantities.

3. All unnecessary motions are to be checked, or prevented. Hence horizontal posture, obscure room, silence, cool air. All the parts of the skin, which feel too hot to the hand, should be exposed to a current of cool air, or bathed with cold water, whether there are eruptions on it or not. Wash the patient

twice a day with cold vinegar and water, or cold falt and water, or cold water alone, by means of a fponge. If fome parts are too cold, as the extremities, while other parts are too hot, as the face or breast, cover the cold parts with slannel, and cool the hot parts by a current of cool air, or bathing them as above.

4. For the healing of ulcers, if in the mouth, folution of alum in water about 40 grains to an ounce, or of blue vitriol in water, one grain or two to an ounce may be used to touch them with three or four times a day. Of these perhaps a solution of alum is to be preserved, as it instantly takes away the stench from ulcers I suppose by combining with the volatile alkali which attends it. For this purpose a solution of alum of an ounce to a pint of water should be frequently injected by means of a syringe into the mouth. If there are ulcers on the external skin, sine powder of bark seven parts, and cerussa in sine powder one part, should be mixed and applied dry on the sore,

and kept on by lint, and a bandage.

As sloughs in the mouth are frequently produced by the previous dryness of the membranes which line it, this dryness should be prevented by frequently moistening them, which may be effected by injection with a syringe, or by a moist sponge, or lastly in the following manner. Place a glass of wine and water, or of milk and sugar, on a table by the bedside, a little above the level of the mouth of the patient; then, having previously moistened a long piece of narrow listing, or cloth, or flannel, with the same liquor, leave one end of it in the glass, and introduce the other into the mouth of the patient; which will thus be supplied with a constant oozing of the sluid through the cloth, which are as a capillary syphon.

The viscid phlegm, which adheres to the tongue, should be coagulated by some austere acid, as by lemon-juice evaporated to half its quantity, or by crab-juice; and then it may be scraped off by a knife, or rubbed off by slannel, or a sage-leaf dipped

in vinegar, or in falt and water.

2. Erysipelas. St. Anthony's fire may be divided into three kinds, which differ in their method of cure, the irritated, the in-

irritated, and the fensitive erysipelas.

Errsfipelas irritatum is attended with increase of irritation befides increase of sensation; that is, with strong, hard and full pulse, which requires frequent venesection, like other inflammations with arterial strength. It is distinguished from the phlegmonic inflammations of the last genus by its situation on the external habit, and by the redness, heat, and tumour, not being distinctly circumscribed; so that the eye or singer cannot exactly trace the extent of them.

When

When the external skin is the feat of inflammation, and produces sensitive irritated fever, no collection of matter is formed, as when a phlegmon is fituated in the cellular membrane beneath the skin; but the cuticle rises as beneath a blister-plaster, and becomes ruptured; and a yellow material oozes out, and becomes inspillated, and lies upon its surface; as is seen in this kind of eryfipelas, and in the confluent small-pox; or if the new veffeis are reabforbed the cuticle peels off in scales. This difference of the termination of eryfipelatous and phlegmonic inflammation feems to be owing in part to the lefs distensibility of the cuticle than of the cellular membrane, and in part to the ready exhalation of the thinner parts of the fecreted fluids through its pores.

This eryfipelas is generally preceded by a fever for two or three days before the eruption, which is liable to appear in fome places, as it declines in others; and feems frequently to arife from a previous scratch or injury of the skin; and is attended fometimes with inflammation of the cellular membrane beneath the skin; whence a real phlegmon and collection of matter become joined to the eryfipelas, and either occasion or increase

the irritated fever, which attends it.

There is a greater sympathy between the external skin and the meninges of the brain, than between the cellular membrane and those meninges; whence erysipelas is more liable to be preceded, or attended, or fucceeded, by delirium than internal phlegmons. I except the mumps, or parotitis, described below; which is properly an external gland, as its excretory duct opens into the air. When pain of the head or delirium precedes the cutaneous eruption of the face, there is some reason to believe, that the primary disease is a torpor of the meninges of the brain; and that the fucceeding violent action is transferred to the skin of the face by fenfitive affociation; and that a fimilar sympathy occurs between some internal membranes and the skin over them, when eryfipelas appears on other parts of the body. If this circumstance should be supported by further evidence, this disease should be removed into Class IV. along with the rheumatism and gout. See Class IV. 1. 2. 17.

This supposed retropulsion of erysipelas on the brain from the frequent appearance of delirium, has prevented the free use of the lancet early in this disease to the destruction of many; as it has prevented the fubduing of the general nflammation, and thus has in the end produced the particular one on the brain. Mr. B-, a delicate gentleman about fixty, had an eryfipelas beginning near one ear, and extending by degrees over the whole head, with hard, full, and strong pulse; blood was taken from him four or five times in considerable quantity, with gentle cathartics, with calomel, diluents, and cool air, and he recovered without any signs of delirium, or inflammation of the meninges of the brain. Mr. W———, a strong corpulent man of inferior life, had erysipelas over his whole head, with strong hard pulse: he was not evacuated early in the disease through the timidity of his apothecary, and died delirious. Mrs. F—— had erysipelas on the face, without either strong or weak pulse; that is, with sensitive fever alone, without superabundance or desciency of irritation; and recovered without any but natural evacuations. From these three cases of erysipelas on the head, it appears that the evacuations by the lancet must be used with courage, where the degree of inflammation requires it; but not where this degree of inflammation is small, nor in the erysipelas attended with inirritation, as described below.

M. M. Venefection repeated according to the degree of inflammation. An emetic. Calomel, three grains every other night. Cool air. Diluents, emetic tartar in fmall dofes, as a quarter of a grain every fix hours. Tea, weak broth, gruel, lem-

onade, neutral falts. See Sect. XII. 6.

Such external applications as carry away the heat of the skin may be of service, as cold water, cold flour, snow, ether. Because these applications impede the exertions of the secerning veffels, which are now in too great action; but any applications of the stimulant kind, as solutions of lead, iron, copper, or of alum, used early in the disease, must be injurious; as they ftimulate the fecerning veffels, as well as the absorbent veffels, into greater action; exactly as occurs when stimulant eye waters are used too foon in ophthalmy. See Class II. 1. 2. 2. But as the cuticle peels off in this case after the inflammation ceases, it differs from ophthalmy; and stimulant applications are not indicated at all, except where symptoms of gangrene appear. For as a new cuticle is formed under the old one, as under a blifter, the ferous fluid between them is a defence to the new cuticle, and should dry into a scab by exhalation rather than be reabsorbed. Hence we see how greafy or oily applications, and even how moist ones, are injurious in erysipelas; because they prevent the exhalation of the ferous effusion between the old and new cuticle, and thus retard the formation of the latter.

Erylipelas inirritatum differs from the former in its being attended with weak pulse, and other symptoms of sensitive inirritated sever. The seet and legs are particularly liable to this erysipelas, which precedes or attends the sphacelus or mortification of those parts. A great and long coldness first affects the limb, and the erysipelas on the skin seems to occur in conse-

quence of the previous torpor of the interior membranes. As this generally attends old age, it becomes more dangerous in proportion to the age, and also to the habitual intemperance of the patient in respect to the use of fermented or spirituous liquor.

When the former kind, or irritated eryfipelas, continues long, the patient becomes fo weakened as to be liable to all the fymptoms of this inirritated eryfipelas; especially where the meninges of the brain are primarily affected. As in that case, after two or three efforts have been made to remove the returning periods of torpor of the meninges to the external skin, those meninges become inslamed themselves, and the patient sinks under the disease; in a manner similar to that in old gouty patients, where the torpor of the liver or stomach is relieved by association of the inslammation of the membranes of the seet, and them of other joints, and lastly the power of association ceasing to act, but the excess of sensation continuing, the liver or stomach remains torpid, or becomes itself inslamed, and the patient is de-

ftroved.

M. M. Where there exists a beginning gangrene of the extremities, the Peruvian bark, and wine, and opium, are to be given in large quantities; fo as to strengthen the patient, but not to intoxicate, or to impede his digestion of aliment, as mentioned in the first species of this genus. Class II. 1. 2. 1. But where the brain is inflamed or oppressed, which is known either by delirium, with quick pulse; or by stupor, and slow respiration with flow pulse; other means must be applied. Such as, first, a fomentation on the head with warm water, with or without aromatic herbs, or falt in it, should be continued for an hour or two at a time, and frequently repeated. A blifter may also be applied on the head, and the fomentation nevertheless occafionally repeated. Internally very gentle stimulants, as camphor one grain or two in infusion of valerian. Wine and water, or fmall beer, weak broth. An enema. Six grains of rhubarb and one of calomel. Afterwards five drops of tincture of opium, which may be repeated every fix hours, if it feems of fervice. Might the head be bathed for a minute with cold water? or with ether? or vinegar?

Erysipelas sensitivum is a third species, differing only in the kind of sever which attends it, which is simply inflammatory, or sensitive, without either excess of irritation, as in the first variety; or the defect of irritation, as in the second variety: all these kinds of erysipelas are liable to return by periods in some people, who have passed the middle of life, as at periods of a lunation, or two lunations, or at the equinoxes. When these periods of erysipelas happen to women, they seem to supply the place of

the receding catamenia; when to men, I have fometimes believed them to be affociated with a torpor of the liver; as they generally occur in those who have drunk vinous spirit excessively, though not opprobriously; and that hence they supply the place of periodical piles, or gout, or gutta rosea.

M. M. As the fever requires no management, the difease takes its progress safely, like a moderate paroxysm of the gout; but in this case, as in some of the former; the erysipelas does not appear to be a primary disease, and should perhaps be re-

moved to the Class of Affociation.

3. Tonfillitis. Inflammation of the tonfils. The uncouth term Cynanche has been used for diseases so dissimilar, that I have divided them into Tonsillitis and Parotitis; and hope to be excused for adding a Greek termination to a Latin word, as one of those languages may justly be considered as a dialect of the other. By tonsillitis the inflammation of the tonsils is principally to be understood; but as all inflammations generally spread further than the part first affected; so, when the summit of the windpipe is also much inflamed, it may be termed tonsillitis trachealis, or croup. See Class I. 1. 3. 4. and II. 1. 2. 4.; and when the summit of the gullet is much inflamed along with the tonsil, it may be called tonsillitis pharyngea, as described in Dr. Cullen's Nosologia, Genus X. p. 92. The inflammation of the tonsils may be divided into three kinds, which require different methods of cure.

Tonfillitis interna. Inflammation of the internal tonfil. When the fwelling is fo confiderable as to produce difficulty of breathing, the fize of the tonfil should be diminished by cutting it with a proper lancet, which may either give exit to the matter it contains, or may make it less by discharging a part of the bleod. This kind of angina is frequently attended with irritated fever besides the fensitive one, which accompanies all inflammation, and fometimes requires venefection. An emetic should be given early in the disease, as by its inducing the retrograde action of the vessels about the fauces during the nausea it occasions, it may eliminate the very cause of the inflammation; which may have been taken up by the absorbents, and still continue in the mouths of the lymphatics or their glands. The patient should then be induced to fwallow fome aperient liquid, as an infusion of fenna, fo as to induce three or four evacuations. Gargles of all kinds are rather hurtful, as the action of using them is liable to give pain to the inflamed parts; but the patients find great relief from frequently holding warm water in their mouths, and putting it out again, or by fyringing warm water into the mouth, as this acts like a warm bath, or fomentation to the inflamed

part. Lastly, some mild stimulant, as a weak solution of falt and water, or of white vitriol and water, may be used to wash the fauces with in the decline of the disease, to expedite the abforption of the new vessels, if necessary, as recommended in

ophthalmy.

Tonfillitis Juperficialis. Inflammation of the furface of the tonfils. As the tonfils and parts in their vicinity are covered with a membrane, which though exposed to currents of air, is nevertheless constantly kept moist by mucus and saliva, and is liable to diseases of its surface like other mucous membranes, as well as to suppuration of the internal substance of the gland; the inflammation of its surface is succeeded by small elevated pustules with matter in them, which soon disappears, and the parts either readily heal, or ulcers covered with sloughs are left on the surface.

This difease is generally attended with only sensitive fever, and therefore is of no danger, and may be distinguished with great certainty from the dangerous inflammation or gangrene of the tonsils at the height of the small-pox, or scarlet sever, by its not being attended with other symptoms of those diseases. One emetic and a gentle cathartic is generally sufficient; and the frequent swallowing of weak broth, or gruel, both without salt in them, relieves the patient, and absolves the cure. When these tumours of the tonsils frequently return I have sometimes suspected them to originate from the absorption of putrid matter from decaying teeth. See Class I. 2. 3. 21. and II. 2. 2. 1.

Tonfillitis inirritata. Inflammation of the tonfils with fensitive inirritated fever is a symptom only of contagious fever, whether attended with scarlet eruption, or with confluent smallpox, or otherwise. The matter of contagion is generally diffused, not diffolved in the air; and as this is breathed over the mucaginous furface of the tonfils, the contagious atoms are liable to be arrested by the tonsil; which therefore becomes the nest of the future difease, like the inflamed circle round the inoculated puncture of the arm in suppositious small-pox. The swelling is liable to fuffocate the patient in small-pox, and to become gangrenous in scarlet fever, and some other contagious fevers, which have been received in this manner. The existence of inflammation of the tonfil previous to the scarlet eruption, as the arm inflames in the inoculated fmall-pox, and suppurates before the variolous eruption, should be a criterion of the fearlet fever being taken in this manner.

M. M. All the means which strengthen the patient, as in the sensitive inirritated sever, Class II. 1. 2. 1. As it is liable to continue a whole lunation or more, great attention should be

used to nourish the patient with acidulous and vinous panada, broth with vegetables boiled in it, fugar, cream, beer; all which given frequently will contribute much to moisten, clean, and heal the ulcufcles, or floughs, of the throat; warm water and wine. or acid of lemon, should be frequently applied to the tonfils by means of a fyringe, or by means of a capillary fyphon, as deferibed in Class II. 1. 2. 1. A flight folution of blue vitriolas two grains to an ounce, or a folution of fugar of lead of about fix grains to an ounce, may be of fervice; especially the latter, applied to the edges of the floughs, drop by drop by means of a small glass tube, or small crow-quill with the end cut off, or by a camel's-hair pencil or sponge; to the end of either of which a drop will conveniently hang by capillary attraction; as folutions of lead evidently impede the progress of ervsipelas on the exterior skin, when it is attended with feeble pulse. Yet a folution of alum injected frequently by a fyringe is perhaps to be preferred, as it immediately removes the fetor of the breath, which must much injure the patient by its being perpetually received into the lungs by respiration.

4. Parotitis. Mumps, or branks, is a contagious inflammation of the parotis and maxillary glands, and has generally been claffed under the word Cynanche or Angina, to which it bears no analogy. It divides itfelf into two kinds, which differ in the degree of fever which attends them, and in the method of cure.

Parotitis suppurans. The suppurating mumps is to be distinguished by the acuteness of the pain, and the sensitive, irritated,

or inflammatory fever, which attends it.

M. M. Venefection. Cathartic with calomel three or four grains repeatedly. Cool air, diluents. This antiphlogistic treatment is to be continued no longer than is necessary to relieve the violence of the pain, as the disease is attended with contagion, and must run through a certain time, like other fevers

with contagion.

Parotitis mutabilis. Mutable parotitis. A fensitive fever only, or a sensitive irritated sever, generally attends this kind. And when the tumour of the parotis and maxillary glands subsides, a new swelling occurs in some distant part of the system; as happens to the hands and feet, at the commencement of the secondary sever of the small-pox, when the tumor of the sace subsides. This new swelling in the parotitis mutabilis is liable to affect the testes in men, and form a painful tumor, which should be prevented from suppuration by very cautious means, if the violence of the pain threaten such a termination; as by bathing the part with coldish water for a time, venesection, a cathartic; or by a blister on the perinæum, or scrotum, or a poultice. When women are affected with this complaint, after the fwelling of the parotis and maxillary glands fubfides, tumor with pain is liable to affect their breafts; which, however, I have nev-

er feen terminate in suppuration.

On the retrocession of the tumor of the testes above described, and I suppose of that of the breasts in women, a delirium of the calm kind is very liable to occur; which in some cases has been the first symptom which has alarmed the friends of the patient; and it has thence been difficult to discover the cause of it without much inquiry; the previous symptoms having been so slight as not to have occasioned any complaints. In this delirium, if the pulse will bear it, venesection should be used, and three or four grains of calomel, with somentation of the head with warm water for an hour together every three or four hours.

Though this disease generally terminates favourably considering the numbers attacked by it, when it is epidemic, yet it is dangerous at other times in every part of its progress. Sometimes the parotis or maxillary glands suppurate, producing ulcers which are difficult to cure, and frequently destroy the patient, where there was a previous scrophulous tendency. The testis in men is also liable to suppurate with great pain, long confinement, and much danger; and lastly, the affection of the

brain is fatal to many.

Mr. W. W. had a swelled throat, which after a few days subsided. He became delirious or stupid, in which state he was dying when I saw him; and his friends ascribed his death to a coup de soleil, which he was said to have received some months

before, when he was abroad.

Mr. A. B. had a fwelling of the throat, which after a few days fubfided. When I faw him he had great stupor, with slow breathing, and partial delirium. On fomenting his head with warm water for an hour these symptoms of stupor were greatly lessend, and his oppressed breathing gradually ceased, and he re-

covered in one day.

Mr. C. D. I found walking about the house in a calm delirium without stupor; and not without much inquiry of his friends could get the previous history of the disease; which had been attended with parotitis, and swelled testis, previous to the delirium. A few ounces of blood were taken away, a gentle cathartic was directed, and his head somented with warm water for an hour, with a small blister on the back, and he recovered in two or three days.

Mr. D. D. came down from London in the coach alone, fo that no previous history could be obtained. He was walking about the house in a calm delirium, but could give no sensible

answers to any thing which was proposed to him. His pulse was weak and quick. Cordials, a blifter, the bark, were in vain exhibited, and he died in two or three days.

Mr. F. F. came from London in the same manner in the coach. He was mildly delirious with confiderable stupor, and moderate pulse, and could give no account of himself. He continued in a kind of cataleptic stupor, so that he would remain for hours in any posture he was placed, either in his chair, or in bed; and did not attempt to speak for about a fortnight, and then gradually recovered. These two last cases are not related as being certainly owing to parotitis, but as they might probably

have that origin.

The parotitis suppurans, or mumps with irritated fever, is at times epidemic among cats, and may be called parotitis felina; as I have reason to believe from the swellings under the jaws, which frequently suppurate, and are very fatal to those animals. In the village of Haywood, in Staffordshire, I remember a whole breed of Persian cats, with long white hair, was destroyed by this malady, along with almost all the common cats of the neighbourhood; and as the parotitis or mumps had not long before prevailed amongst human beings in that part of the country, I recollect being inclined to believe, that the cats received the infection from mankind; though in all other contagious difeases, except the rabies canina can be so called, no different genera of animals naturally communicate infection to each other; and I am informed, that vain efforts have been made to communicate the fmall-pox and measles to some quadrupeds by inoculation. A difease of the head and neck destroyed almost all the cats in Westphalia. Savage, Nosol. Class X. Art. 30. 8.

Since the above was first published, the cow-pox, various vaccinæ, has been fuccessfully inoculated on the human subject, and produced a difease in some respects similar to the small-pox:

See Variola.

5. Catarrhus fensitivus confists of an inflammation of the membrane, which lines the nostrils and fauces. It is attended with fensitive fever alone, and is cured by the steam of warm water externally, and by diluents internally, with moderate venefection and gentle cathartics. This may be termed catarrhus fensitivus, to distinguish it from the catarrhus contagiosus, and is in common language called a violent cold in the head; it differs from the catarrhus calidus, or warm catarrh, of Class I. 1. 2. 7. in the production of new vessels, or inflammation of the membrane, and the confequent more purulent appearance of the discharge.

Raucedo catarrhalis, or catarrhal hoarseness, isa frequentsymp-

tom of this disease, and is occasioned by the pain or foreness which attends the thickened and inflamed membranes of the larynx; which prevents the muscles of vocality from sufficiently contracting the aperture of it. It ceases with the inflammation, or may be relieved by the steam of warm water alone, or of water and vinegar, or of water and ether. See Paralytic Hoarseness, Class III. 2. 1. 4.

6. Catarrhus contagicius. This malady attacks fo many at the fame time, and spreads gradually over so great an extent of country, that there can be no doubt but that it is disseminated by the atmosphere. In the year 1782 the sun was for many weeks obscured by a dry sog, and appeared red as through a common mist. The material, which thus rendered the air muddy, probably caused the epidemic catarrh, which prevailed in that year, and which began far in the north, and extended itself over all Europe. See Botanic Garden, Vol. II. note on Chunda, and Vol. I. Canto IV. line 294, note; and was supposed to have been discharded to have been dead to have been dea

volcano, which much displaced the country of Iceland.

In many instances there was reason to believe that this disease became contagious, as well as epidemic; that is, that one person might receive it from another, as well as by the general unfalutary influence of the atmosphere. This is difficult to comprehend, but may be conceived by confidering the increase of contagious matter in the fmall-pox. In that difease one particular of contagious matter stimulates the skin of the arm in inoculation into morbid action fo as to produce a thousand particles similar to itself; the same thing occurs in catarrh, a few deleterious atoms stimulate the mucous membrane of the nostrils into morbid actions, which produce a thousand other particles similar to themselves. These contagious particles diffused in the air must have confifted of animal matter, otherwife how could an animal body by being stimulated by them produce similar particles? Could they then have had a volcanic origin, or must they not rather have been blown from putrid marshes full of animal matter? But the greatest part of the solid earth has been made from animal and vegetable recrements, which may be dispersed by volcanoes.—Future discoveries must answer these questions.

As the fensitive fever attending these epidemic catarrhs is seldom either much irritated or inirritated, venesection is not always either clearly indicated or forbidden; but as those who have died of these catarrhs have generally had inflamed livers, with consequent suppuration in them, venesection is advisable, wherever the cough and sever are greater than common, so as to render the use of the lancet in the least dubious. And in some cases a second bleeding was necessary, and a mild cathartic or two

have

with four grains of calomel; with mucilaginous fubacid diluents; and warm steam occasionally to alleviate the cough, finished the cure.

The catarrhus contagiofus is a frequent difeafe amongst horses and dogs; it seems first to be different amongst these animals by miasmata diffused in the atmosphere, because so many of them receive it at the same time; and afterwards to be communicable from one horse or dog to another by contagion, as above described. These epidemic or contagious catarrhs more frequently occur amongst dogs and horses than amongst men; which is probably owing to the greater extension and sensibility of the mucous membrane, which covers the organ of smell, and is diffused over their wide nostrils, and their large maxillary and frontal cavities. And to this circumstance may be ascribed the

greater fatality of it to these animals.

In respect to horses, I suspect the fever at the beginning to be of the fensitive, irritated, or inflammatory kind, because there is fo great a discharge of purulent mucus; and that therefore they will bear once bleeding early in the difease; and also one mild purgative, confifting of about half an ounce of aloe, and as much white hard foap, mixed together. They should be turned out to grass both day and night for the benefit of pure air, unless the weather be too cold (and in that case they should be kept in an open airy stable, without being tied), that they may hang down their heads to facilitate the discharge of the mucus from their nostrils. Grass should be offered them, or other fresh vegetables, as carrots and potatoes, with mashes of malt, or of oats, and with plenty of fresh warm or cold water frequently in a day. When fymptoms of debility appear, which may be known by the coldness of the ears or other extremities, or when sloughs can be feen on the membrane, which lines the nostrils, a drink confifting of a pint of ale with half an ounce of tincture of opium in it, given every fix hours, is likely to be of great utility.

In dogs I believe the catarrh is generally joined with fymptoms of debility early in the disease. These animals should be permitted to go about in the open air, and should have constant access to fresh water. The use of being as much as may be in the air is evident, because all the air, which they breathe, passes twice over the putrid sloughs of the mortissed parts of the membrane, which lines the nostrils, and the maxillary and frontal cavities; that is, both during inspiration and expiration; and must therefore be loaded with contagious particles. Fresh new milk, and fresh broth, should be given them very frequently, and they should be suffered to go amongst the grass, which they sometimes eat for the purpose of an emetic; and if possible should

have access to a running stream of water. As the contagious mucus of the nostrils, both of these animals and of horses, generally drops into the water, they attempt to drink. Bits of raw stess, if the dog will eat them, are preferred to cooked meat; and from five to ten drops of tincture of opium may be given with advantage, when symptoms of debility are evident, according to the fize of the dog every six hours. If sloughs can be seen in the nostrils, they should be moistened twice a day, both in horses and dogs, with a solution of sugar of lead, or of alum, by means of a sponge sixed on a bit of whale-bone, or by a syringe. The lotion may be made by dissolving half an ounce of sugar of

lead, or of alum, in a pint of water.

Ancient philosophers seem to have believed, that the contagious miasmata in their warm climates affected horses and dogs previous to mankind. If those contagious particles were supposed to be diffused amongst the heavy inflammable air, or carbonated hydrogen, of putrid marshes, as these animals hold their heads down lower to the ground, they may be supposed to have received them sooner than men. And though men and quadrupeds might receive a disease from the same source of marsh-putresaction, they might not afterwards be able to insect each other, though they might insect other animals of the same genus; as the new contagious matter generated in their own bodies might not be precisely similar to that received; as happened in the jail-fever at Oxford, where those who took the contagion and died, did not insect others.

On mules and dogs the infection first began, And, last, the vengeful arrows fix'd on man. Pore's Homer's lliad, L.

7. Peripneumonia superscialis. The superscial or spurious peripneumony consists in an inflammation of the membrane, which lines the bronchia, and bears the same analogy to the true peripneumony, as the inflammation of other membranes do to that of the parenchyma, or substantial parts of the viscus, which they surround. It affects elderly people, and frequently occasions their death; and exists at the end of the true peripneumony, or along with it; when the lancet has not been used sufficiently to cure by reabsorbing the inflamed parts, or what is termed by resolution.

M. M. Diluents, mucilage, antimonials, warmish air constantly changed, venesection once, perhaps twice, if the pulse will bear it. Oily volatile draughts. Balsams? Neutral salts increase the tendency to cough. Blisters in succession about the chest. Warm bath. Mild purgatives. Very weak chicken

broth

broth without falt in it. Boiled onions. One grain of calomel every night for a week. From five drops to ten of tincture of opium at fix every night, when the patient becomes week.

Digitalis? See Class II. 1. 6. 7.

8. Pertuffis. Tuffis convultiva. Chin-cough refembles peripneumonia fuperficialis in its confuffing in an inflammation of the membrane which lines the air-veffels of the lungs; but differs in the circumstance of its being contagious; and is on that account of very long duration; as the whole of the lungs are probably not infected at the fame time, but the contagious inflammation continues gradually to creep on the membrane. It may in this respect be compared to the ulcers in the pulmonary consumption; but it differs in this, that in chin-cough some branches of the bronchia heal, as others become inflamed.

This complaint is not usually classed amongst febrile disorders. but a fensitive fever may generally be perceived to attend it during some part of the day, especially in weak patients. And a peripneumony very frequently supervenes, and destroys great numbers of children, except the lancet or four or fix leeches be immediately and repeatedly used. When the child has permanent difficulty of breathing, which continues between the coughing fits: unless blood be taken from it, it dies in two, three, or four days of the inflammation of the lungs. During this permanent difficulty of breathing, the hooping cough abates, or quite ceases, and returns again after once or twice bleeding; which is then a good fymptom, as the child now possessing the power to cough shews the difficulty of breathing to be abated. I dwell longer upon this, because many lose their lives from the difficulty there is in bleeding young children; where the apothecary is old or clumfy, or is not furnished with a very sharp and fine pointed lancet. In this distressing situation the application of four leeches to one of the child's legs, the wounds made by which should continue to bleed an hour or two, is a succedaneum; and faves the patient, if repeated once or twice, according to the difficulty of the respiration.

The chin-cough feems to refemble the gonorrhæa venerea in feveral circumstances. They are both received by infection, are both diseases of the mucous membrane, are both generally cured in four or six weeks without medicine. If ulcers in the cellular membrane under the mucous membrane occur, they are of a phagedenic kind, and destroy the patient in both diseases, if no

medicine be administered.

Hence the cure should be similar in both these diseases; first general evacuations and diluents, then, after a week or two, I have believed the following pills of great advantage. The dose

for a child of about three years old was one-fixth part of a grain of calomel, one-fixth part of a grain of opium, and two grains

of rhubarb, to be taken twice a day.

The opium promotes absorption from the mucous membrane, and hence contributes to heal it. The mercury prevents ulcers from being formed under the mucous membrane, or cures them, as in the lues venerea; and the rhubarb is necessary to keep

the bowels open.

M. M. Antimonial vomits frequently repeated. Mild catharties. Cool air. Tincture of cantharides, or repeated blifters; afterwards opiates in small doses, and the bark. Warm bath frequently used. The steam of warm water with a little vinegar in it may be inhaled twice a day. Thirty drops of faturated tincture of digitalis puerpurea, purple foxglove, were given twice a day to a lady, seventy years of age, in this disease, with great and almost immediate advantage. I have fince given from five to ten drops twice a day to two children, with also great apparent advantage. See Art. IV. 2. 3. 7. Arsenic has lately been recommended in the hooping cough. See Art. IV. 2. 6. 9. And externally a folution of 20 grains of emetic tartar, antimonium tartarifatum, in two ounces of water, to which is to be added one ounce of tincture of cantharides, is recommended, by Dr. Struve of America, to be rubbed very frequently on the region of the stomach. Could the breathing of carbonic acid gas mixed with atmospheric air be of service? Copious venefection, when a difficulty of breathing continues between the fits of coughing; otherwise the cough and the expectoration cease, and the patient is destroyed. Ulcers of the lungs fometimes supervene, and the phthitis pulmonalis in a few weeks terminates in death. Where the cough continues after fome weeks without much of the hooping, and a fenfitive fever daily supervenes, so as to resemble hectic fever from ulcers of the lungs; change of air for a week or fortnight acts as a charm, and restores the patient beyond the hopes of the physician.

Young children should lie with their heads and shoulders raised; and should be constantly watched day and night; that when the cough occurs, they may be held up easily, so as to stand upon their feet bending a little forwards; or nicely supported in that posture which they feem to put themselves into. Abow of whalebone, about the size of the bow of a key, is very useful to extract the phlegm out of the mouths of infants at the time of their coughing; as a handkerchief, if applied at the time of their quick inspirations after long holding their breath is dangerous, and may suffocate he patient in an instant, as I believe has sometimes happened.

9. Variola discreta. The small-pox is well divided by Syden-Vol. II. C c ham

ham into distinct and confluent. The former consists of distinct pustules, which appear on the fourth day of the fever, are circumferibed and turgid; the fever ceasing when the eruption is complete. Head-ach, pain in the loins, vomiting frequently,

and convulfive fits fometimes, precede the eruption.

The diftinct fmall-pox is attended with fensitive fever only, when very mild, as in most inoculated patients; or with sensitive irritated sever, when the disease is greater: the danger in this kind of small-pox is owing either to the tumor and soreness of the throat about the height, or eighth day of the eruption; or to the violence of the secondary sever. For, first, as the natural disease is generally taken by particles of the dust of the contagious matter dried and floating in the air, these are liable to be arrested by the mucus about the throat and tonsils in their passage to the lungs, or to the stomach, when they are previously mixed with faliva in the mouth. Hence the throat inslames like the arm in inoculated patients; and this increasing, as the disease advances, destroys the patient about the height.

Secondly, all those upon the face and head come out about the same time, namely, about one day before those on the hands, and two before those in the trunk; and thence, when the head is very full, a danger arises from the secondary sever, which is a purulent not a variolous sever; for as the matter from all these of the sace and head is reabsorbed at the same time, the patient is destroyed by the violence of this purulent sever; which in the distinct small-pox can only be abated by venesection and catharties; but in the confluent small-pox requires cordials and opiates, as it is attended with arterial debility. See Sect. XXXV.

1. and XXXIII. 2. 10.

When the puffules on the face recede, the face fwells; and when those of the hands recede, the hands fwell; and the same of the feet in succession. These swellings seem to be owing to the absorption of variolous matter, which by its stimulus excites the cutaneous vessels to secrete more lymph, or serum, or mucus, exactly as happens by the stimulus of a blister. Now, as a blister sometimes produces strangury many hours after it has risen, it is plain, that a part of the cantharides is absorbed, and carried to the neck of the bladder; whether it enters the circulation, or is carried thither by retrograde movements of the urinary branch of lymphatics; and by parity of reasoning the variolous matter is absorbed, and swells the face and hands by its stimulus.

Variola confluens. The confluent finall-pox confits of numerous putules, which appear on the third day of the fever, flow together, are irregularly circumferibed, flaccid, and little elevated; the fever continuing after the eruption is complete; con-

vulsions do not precede this kind of fmall-pox, and are so far to

be esteemed a favourable symptom.

The confluent small-pox is attended with sensitive inirritated fever, or inflammation with arterial debility; whence the danger of this disease is owing to the general tendency to gangrene, with petechiæ, or purple spots, and hæmerrhages; besides the two sources of danger from the tumor of the throat about the height, or eleventh day of the eruption, and the purulent sever after that time; which are generally much more to be dreaded

in this than in the distinct small-pox described above.

M. M. The method of treatment must vary with the degree and kind of fever. Venefection may be used in the distinct fmall-pox early in the disease, according to the strength or hardness of the pulse; and perhaps on the first day of the confluent fmall-pox, and even of the plague, before the fenforial power is exhausted by the violence of the arterial action? Cold air, and even washing or bathing in cold water, is a powerful means in perhaps all eruptive difeases attended with fever; as the quantity of eruption depends on the quantity of the fever, and the activity of the cutaneous vessels; which may be judged of by the heat produced on the skin; and which latter is immediately abated by exposure to external cold. Mercurial purges, as three grains of calomel repeated every day during the eruptive fever, fo as to induce three or four stools, contribute to abate inflammation; and is believed by fome to have a specific effect on the variolous, as it is supposed to have on the venereal contagion.

It has been faid, that opening the pock and taking out the matter has not abated the fecondary fever; but as I had conceived, that the pits, or marks, left after the small-pox, were owing to the acrimony of the matter beneath the hard scabs, which not being able to exhale eroded the skin, and produced ulcers, I directed the faces of two patients in the confluent small-pox to be covered with cerate early in the difease, which was daily renewed; and I was induced to think, that they had much lefs of the fecondary fever, and were fo little marked, that one of them, who was a young lady, almost entirely preserved her beauty. Perhaps mercurial plasters, or cerates, made without turpentine in them, might have been more efficacious in preventing the marks, and especially if applied early in the disease, even on the first day of the eruption, and renewed daily. For it appears from the experiments of Van Woensel, that calomel or corrofive fublimate, triturated with variolous matter, incapacitates it from giving the disease by inoculation. Calomel or fublimate given as an alterative for ten days before inoculation, and till the eruptive fever commences, is faid with certainty, to render

render the disease mild by the same author. Exper. on Mercury by Van Woenfel, translated by Dr. Fowle, Salisbury.

C. Desfarts, in the fitting of the French national institute is faid to have adduced a number of facts to prove, that the natural fmall-pox is rendered much milder by the use of mercurial remedies; which I suppose is probably true, as mercurials increase the absorption in many other ulcers, and consequently diminish the acrimony of the matter, and forward their healing.

Variola inoculata. The world is much indebted to the great discoverer of the good effects of inoculation, whose name is unknown; and our own country to lady Wortley Montague for its introduction into this part of Europe. By inferting the variolous contagion into the arm, it is not received by the tonfils, as generally happens, I suppose, in the natural small-pox; whence there is no dangerous fwelling of the throat, and as the pultules are generally few and diffinct, there is feldom any fecondary fever; whence those two sources of danger are precluded; hence when the throat in inoculated finall-pox is much inflamed and fwelled, there is reason to believe, that the disease had been previously taken by the tonfils in the natural way: which alfo, I fuppose, has generally happened, where the confluent

kind of fmall-pox has occurred on inoculation.

I have known two instances, and have heard of others, where the natural fmall-pox began fourteen days after the contagion had been received; one of these instances was of a countryman, who went to a market-town many miles from his home, where he faw a person in the small-pox, and on returning the sever commenced that day fortnight: the other was of a child, whom the ignorant mother carried to another child ill of the small-pox, on purpose to communicate the disease to it; and the variolous fever began on the fourteenth day from that time. So that in both these cases sever commenced in half a lunation after the contagion was received. In the inoculated fmall-pox the fever generally commences on the feventh day; or after a quarter of a lunation; and on this circumstance probably depends the greater mildness of the latter. The reason of which is difficult to comprehend; but supposing the facts to be generally as above related, the flower progress of the contagion indicates a greater inirritability of the fystem, and in consequence a tendency to malignant rather than to inflammatory fever. This difference of the time between the reception of the infection and the fever in the natural and artificial fmall-pox may nevertheless depend on its being inferted into a different feries of veffels; or to some unknown effect of lunar periods. It is a subject of great curiofity, and deferves further investigation.

When

When the inoculated fmall-pox is given under all the most favourable circumstances, I believe less than one in a thousand mifcarry, which may be afcribed to fome unavoidable accident, fuch as the patient having previously received the infection, or being about to be ill of some other disease. Those which have lately miscarried under inoculation, as far as has come to my knowledge, have been chiefly children at the breaft; for in these the habit of living in the air has been confirmed by fo short a time, that it is much easier destroyed, than when these habits of life have been established by more frequent repetition. See Sect. XVII. 3. Thus it appears from the bills of mortality kept in the great cities of London, Paris, and Vienna, that out of every thousand children above three hundred and fifty die under two years old. (Kirkpatrick on Inoculation.) Whence a strong reason against our hazarding inoculation before that age is passed, especially in crowded towns; except where the vicinity of the natural contagion renders it necessary, or the convenience of inoculating a whole family at a time; as it then becomes better to venture the less favourable circumstances of the age of the patient, or the chance of the pain from toothing, than to risk the infection in the natural way.

The most favourable method consists in, first, for a week before inoculation, restraining the patients from all kinds of fermented or spirituous liquor, and from animal food; and by giving them from one grain to three or four of calomel every other day for three times. But if the patients be in any the least danger of taking the natural infection, the inoculation had better be immediately performed, and this abstinence then begun; and two or three gentle purges with calomel should be given, one immediately, and on alternate days. These cathartics should not induce more than two or three stools. I have seen two instances of a confluent small-pox in inoculation following a violent purging induced by too large a dose of calomel.

Secondly, the matter used for inoculation should be in a small quantity, and warm, and sluid. Hence it is best when it can be recently taken from a patient in the disease; or otherwise it may be diluted with part of a drop of warm water, since its sluidity is likely to occasion its immediate absorption; and the wound should be made as small and superficial as possible, as otherwise ulcers have been supposed sometimes to ensue with subaxillary abscesses. Add to this, that the making two punctures either on the same or one on each arm, secures the success of the operation in respect to communicating the infection.

Thirdly, at the time of the fever or eruption, the application of cool air to those parts of the skin which are too warm, or ap-

pear red, or are covered with what is termed a rash, should be used freely, as well as during the whole disease. And at the same time, if the seet or hands are colder than natural, these should be covered with sannel. See Class IV. 2. 2. 10.

Where the matter used is not procured quite fresh, the manner of preserving it should be nicely attended to: as I have been informed that a surgeon procured some matter in a sluid state, about a tea-spoonful, which had been kept some time in a quill, and afterwards in a small phial, which he carried sixteen hours in his breeches-pocket; with this he inoculated many children, most of whom had not the small-pox in consequence, but were affected with typhus, one of whom died. Whence it appears, that the variolous matter had undergone by putresaction a decomposition, and that another kind of contagious material had been produced; which agrees with the ingenious observations of Dr. Jenner, in his treatises on the variolæ vaccinæ, or cowpox; and of Mr. Kite, related in the Memoirs of the Medical Society of London, Vol. IV.

May not the confluent fmall-pox proceed from the contagious matter having undergone a partial putrefaction, so as to contain both the variolous and the typhus contagion? and that, whether the disease be taken naturally or by inoculation? and that hence the confluent kind consists of the small-pox, with the sever commonly termed putrid? and that, lastly, as Dr. Jenner observes, where the small-pox has been said to recede, or not to rise, the disease has been simply a malignant or typhus sever, febris sensa-

tiva inirritata, mistaken for the small-pox?

Variola vaccina. Cow-pox. Cows are liable to an eruption on their paps or udders, in some counties, as in Gloucestershire; which was occasionally communicated to the hands or arms of those who milked them, producing an ulcer, and some degree of fever: and it had been long observed by the people of those counties, that those who had undergone this disease, which was

called the cow-pox, were not liable to the fmall-pox.

Dr. Jenner, an eminent physician in Gloucestershire, fortunately attended to this disease, found it to be much milder than the small-pox, and that the fact was true, that it secured those who had been insected with it from afterwards being liable to the variolous insection. He also observed, that the vaccine-pox is not insectious, but by careful inoculation; and that, on this account, it might be inoculated in a family, without endangering others. A circumstance of great consequence to the public, as the inoculation of the small-pox is known frequently to propagate that disease; and also to private families, when there happens to be a pregnant woman in them, who has not had the small pox

become

fmall-pox: to all whom in that fituation it is dangerous, as it generally produces mifcarriage, and frequently death. Dr. Cappe, in an ingenious paper in the York Herald, observes, that the vaccine disease is never communicated but by contact, and then only when the matter lies on the broken skin; and that many women during pregnancy have passed through this disease, and none have suffered from it; and that instead of being peculiarly dangerous to young infants, as the small-pox is, it seems to be peculiarly mild to them.

From all these circumstances it may be hoped, that the inoculation of the cow-pox may become so general, and performed so early in life, as totally to eradicate the small-pox; by which latter disease above two thousand persons are shewn by Dr. Cappe, by the bills of mortality, to be annually destroyed in a

part of London only.

As the cow-pox is so much less infectious than the small-pox, it requires much more care in the inoculation to give the disease with certainty; whence it sometimes has happened, that a slight inflammation from the puncture of the lancet has been mistaken by the unskilful for the vaccine disease: and I have heard of four such patients in this country who have afterward taken the small-pox. But as Dr. Woodville inoculated a thousand people with the small-pox, who had previously received the cow-pox, without one of them taking the infection, there can be no doubt but that the four patients above mentioned had not previously undergone the vaccine disease; and ought not therefore to discredit this fortunate and wonderful discovery.

In the counties where the cows are subject to this disease, the milking is performed principally by men-fervants; and it is there believed, as Dr. Jenner mentions, that the disease was previously given to the paps of the cows by the hands of the men who milked them, and who had previously acquired the infectious matter from the heels of horses, which discharged an acrid fanies, when they had a difease called the grease. This may be worth further investigation; as the preservation of people from the small-pox, by their having undergone the cow-pox, is so wonderful a phenomenon, fo contrary to our previous knowledge of any analogy between the infectious difeases of men and quadrupeds, that other facts equally furprifing may exist. May not the fmall-pox have been originally acquired from the cow-pox? which latter, having been a much older difease, may by process of time have become milder than the former: as the fmall-pox is believed also to have become much milder than formerly; owing probably to the incapacity of receiving it, which exists in those who have undergone that disease, having in process of time

become hereditary. Which incapacity of receiving a fecond time the small pox may be explained from the general law of animation, that stimuli greater than natural lose their effect by habit, or from their being too violently or too frequently applied.

As the cow-pox is faid to be fo favourable to infants, great benefit might accrue to mankind by their early inoculation, which might in time exterminate the fmall-pox. This might be perhaps effected by establishing a dispensary in towns, and even villages, and allowing a premium of a few shillings to every one of the poor who should be thus inoculated, as well as their daily sustenance for eight or ten days, that their arms might be inspected by a surgeon, to ascertain that they underwent the genuine disease.

10. Rubeola irritata, morbilli. The measles commence with fneezing, red eyes, dry hoarse cough, and are attended with sensitive irritated sever. On the fourth day, or a little later, small thick eruptions appear, scarcely eminent above the skin, and, as-

ter three days, changing into very fmall branny fcales.

As the contagious material of the small-pox may be supposed to be dissufficient in the air like a fine dry powder, and mixing with the saliva in the mouth to insect the tonsils in its passage to the stomach; so the contagious material of the measses may be supposed to be more completely dissolved in the air, and thus to impart its poison to the membrane of the nostrils, which covers the sense of smell; whence a catarrh with sneezing ushers in the sever; the termination of the nasal duct of the lachrymal sac is subject to the same stimulus and inflammation, and affects by sympathy the lachrymal glands, occasioning a great flow of tears. See Sect. XVI. 8. And the redness of the eye and eyelids is produced in consequence of the tears being in so great quantity, that the saline part of them is not entirely reabsorbed. See Sect. XXIV. 2. 8.

The contagion of the measles, if it be taken a sufficient time before inoculation, so that the eruption may commence before the variolous sever comes on, stops the progress of the small-pox in the inoculated wound, and delays it till the measle-sever has

finished its career. See Sect. XXXIII. 2. 9.

The measles are usually attended with inflammatory fever with strong pulse, and bear the lancet in every stage of the disease. In the early periods of it, venesection renders the sever and cough less; and, if any symptoms of peripneumony occur, is repeatedly necessary; and at the decline of the disease, if a cough be left after the eruption has ceased, and the subsequent branny scales are falling of, venesection should be immediately used; which prevents the danger of consumption. At this time

also change of air is of material consequence, and often removes the cough like a charm, as mentioned in a similar situation at the end of the chin-cough.

Rubeola inirritata. Measles with inirritated fever, or with weak pulse, has been spoken of by some writers. See London Med. Observ. Vol. IV. Art. XI. It has also been said to have been attended with fore throat. Edinb. Essays, Vol. V. Art. II. Could the scarlet sever have been mistaken for the measles? or might one of them have succeeded the other, as in the measles

and fmall-pox mentioned in Sect. XXXIII. 2. 9. ?

From what has been faid, it is probable that inoculation might difarm the measles as much as the small-pox, by preventing the catarrh, and frequent pulmonary inflammation, which attends this difease; both of which are probably the consequence of the immediate application of the contagious miasmata to these membranes. Some attempts have been made, but a difficulty seems to arise in giving the disease; the blood, I conjecture, would not infect, nor the tears; perhaps the mucous discharge from the nostrils might succeed; or a drop of warm water put on the eruptions, and scraped off again with the edge of a lancet; or if the branny scales were collected, and mostlened with a little warm water? Further experiments on this subject would be worthy the public attention.

11. Scarlatina mitis. The scarlet fever exists with all degrees of virulence, from a flea-bite to the plague. The infectious material of this disease, like that of the small-pox, I suppose to be diffused, not dissolved, in the air; on which account I sufpect that it requires a much nearer approach to the fick for a well person to receive the infection, than in the measles; the contagion of which I believe to be more volatile, or diffufible, in the atmosphere. But as the contagious miasmata of smallpox and scarlet fever are supposed to be more fixed, they may remain for a longer time in clothes or furniture; as a thread dipped in variolous matter has given the difeafe by inoculation after having been exposed many days to the air, and after having been kept many months in a phial. This also accounts for the slow or fporadic progress of the scarlet fever, as it infects others at but a very small distance from the sick; and does not produce a quantity of pus-like matter, like the fmall-pox, which can adhere to the clothes of the attendants, and when dried is hable to be shaken off in the form of powder, and thus propagate the

This contagious powder of the finall-pox, and of the scarlet fever, becomes mixed with faliva in the mouth, and is thus carried to the tonfils, the mucus of which arrests some particles of this deleterious material; while other parts of it are carried into the stomach, and are probably decomposed by the power of digestion; as seems to happen to the venom of the viper, when taken into the stomach. Our perception of bad tastes in our mouths, at the same time that we perceive disagreeable odours to our nostrils, when we inhale very bad air, occasions us to spit out our faliva; and thus in some instances, to preserve ourselves from infection. This has been supposed to originate from the sympathy between the organs of taste and smell; but any one who goes into a sick-room close shut up, or into a crowded assembly-room, or tea-room, which is not sufficiently ventilated, may easily mix the bad air with the saliva on his tongue so as to taste it; as I have myself frequently attended to.

Hence it appears that these heavy infectious matters are more liable to mix with the saliva, and inflame the tonsils, and that either before or at the commencement of the sever; and this is what generally happens in the scarlet sever, always I suppose in the malignant kind, and very frequently in the mild kind. But as this infection may be taken by other means, as by the skin, it also happens in the most mild kind, that there is no inflammation of the tonsils at all; in the same manner as there is generally no inflammation of the tonsils in the inoculated small-pox.

In the mild fearlatina on the fourth day of the fever the face fwells a little, at the fame time a florid redness appears on various parts of the skin in large blotches, at length coalescing, and

after three days changing into branny scales.

M. M. Cool air. Fruit. Lemonade. Milk and water.

Scarlatina maligna. The malignant fearlet fever begins with inflamed tonfils; which are fucceeded by dark drab-coloured floughs from three to five lines in diameter, flat, or beneath the furrounding furface; and which conceal beneath them fpreading gangrenous ulcers. The fwellings of the tonfils are fenfible to the eye and touch externally, and have an elaftic rather than an ecdematous feel, like parts in the vicinity of gangrenes. The pulfe is very quick and weak, with delirium, and the patient generally dies in a few days; or if he recovers, it is by flow degrees, and attended with anafarca.

M. M. A vomit once. Wine. Beer. Cyder. Opium. Bark, in small repeated doses. Small successive blisters, if the extremities are cooler than natural. Cool air on the hot parts of the skin, the cool extremities being at the same time covered. Iced lemonade. Broth. Custards. Milk. Jellies. Bread pudding. Chicken. Touch the ulcers with a dry sponge to absorb the contagious matter, and then with a sponge filled with vinegar, with or without sugar of lead dissolved in it, about six

grains

grains to an ounce; or with a very little blue vitriol dissolved in it, as a grain to an ounce; but nothing so instantaneously corrects the putrid smell of ulcers as a solution of alum, about half an ounce to a pint of water, which should be a little warmish, and injected into the fauces gently by means of a syringe. These should be repeated frequently in a day, if it can be done easily, and without fatigue to the child. A little powder of bark taken frequently into the mouth, as a grain or two, that it may mix with the saliva, and thus frequently stimulate the dying tonsils. Could a warm bath made of decoction of bark, or a cold alluviation with it, be of service? Could oxygene gas mixed with common air stimulate the languid system? Small electric shocks through the tonsils every hour? ether frequently

applied externally to the fwelled tonfils?

As this disease is attended with the greatest degree of debility, and as stimulant medicines, if given in quantity, so as to produce more than natural warmth, contribute to expend the already too much exhausted sensorial power; it appears, that there is nothing fo necessary to be nicely attended to as to prevent any unnecessary motions of the system; this is best accomplished by the application of cold to those parts of the skin, which are in the least too hot. Dr. Mosman, of Bradford, directed a boy of eight years of age, who was very hot, and covered with the fcarlet eruption, to be taken naked out of bed, and moistened his skin all over with cold vinegar, by means of a sponge, with great and good event. It is probable that cold vinegar might diminish the inflammation and confequent heat of the skin more effectually than cold water, as its application to the lips renders them pale, probably by stimulating the absorbent extremities of the veins into greater action. Annals of Medicine, Vol. IV. 1799. Secondly, that the exhibition of the bark in fuch quantity as not to oppress the stomach and injure digestion, is next to be attended to, as not being liable to increase the actions of the fystem beyond their natural quantity; and that opium and wine should be given with the greatest caution, in very small repeated quantity, and so managed as to prevent, if possible, the cold fits of fever; which probably occur twice in 25 hours, obeying the lunations like the tides, as mentioned in Sect. XXXII. 6. that is, I suppose, the cold periods, and consequent exacerbations of fever, in this malignant scarlatina, occur twice in a lunar day; which is about ten minutes less than 25 hours; so that if the commencement of one cold fit be marked, the commencement of the next may be expected (if not disturbed by the exhibition of wine, or opium, or the application of blifters) to occur in about twelve

twelve hours and a half from the commencement of the former;

or if not prevented by large doses of the bark.

No one could do an act more beneficial to fociety, or glorious to himfelf, than by teaching mankind how to inoculate this fatal difeafe; and thus to deprive it of its malignity. Matter might be taken from the ulcers in the throat, which would probably convey the contagion; or warm water might be put on the eruption, and fcraped off again by the edge of a lancet. These experiments could be attended with no danger, and should be tried for the public benefit, and the honour of medical science.

Dr. Harwood, professor of anatomy, at Cambridge, favoured me with the following curious case of this infection: Mr. N—had a violent delirium in the scarlet sever, with the skin cracked in many places, exuding an ichorous matter; he was attended by a poor man who had recently cut his hand with a glass bottle, and in the struggle of confining him to bed his wounded hand was frequently applied to the patient's body. This happened on the Friday night; his hand was inslamed and the arm swelled the next day; on the Monday following he was seized with the same sever, and died on the Wednesday morning after. This would seem to shew, as far as a single case can be relied on, that the scarlet sever may be communicated, like the small-pox, by inoculation, and probably with similar success, if the matter be diluted with warm water, used in small quantity, and by superficial incisions only, through the cuticle.

12. Miliaria. Miliary fever. An eruption produced by the warmth, and more particularly by the stimulus, of the points of the wool in flannel or blankets applied to the skin, has been frequently observed; which, by cool dress, and bed-clothes without flannel, has soon ceased. See Class I. 1. 2. 3. This, which may be called miliaria sudatoria, has been consounded with other miliary severs, and has made the existence of the latter doubted. Two kinds of eruptions I have seen formerly attended with fever, but did not sufficiently mark their progress, which I conceived to be miliary eruptions, one with arterial strength, or with sensitive irritated sever, and the other with arterial debility,

or with fensitive inirritated fever.

In the former of these, or miliaria irritata, the eruptions were distinct and larger than the small-pox, and the sever was not subdued without two or three venescritons, and repeated cathartics with calomel.

The latter, or *miliaria inirritata*, was attended with great arterial debility; and during the course of the sever pellucid points appeared within the skin, particularly on the soft parts of the singers. And, in one patient, whom I esteemed near her end,

I well recollect to have observed round pellucid globules, like what are often seen on vines in hot-houses, no larger than the smallest pins' heads, adhere to her neck and bosom; which were hard to the touch, but were easily rubbed off. These diseases, if they are allied, do not differ more than the kinds of small-pox; but require many further observations.

The eruption so often seen on children in the cradle, and called by the nurses red-gum, and which is attended with some degree of sever, I suspect to be produced by too great warmth, and the contact of slannel next their tender skins, like the miliaria sudatoria; and like that requires cool air, cool clothes, and lin-

en next their skin.

13. Peftis. The plague, like other difeases of this class, seems to be sometimes mild, and sometimes malignant; according to the testimony of different writers. It is said to be attended with inflammation, with the greatest arterial debility, and to be very contagious, attended at an uncertain time of the sever with buboes and carbuncles. Some authors affirm, that the contagion of the plague may be repeatedly received, so as to produce the disease; but as this is contrary to the general analogy of all contagious diseases, which are attended with sever, and which cure themselves spontaneously; there is reason to suspect, that where it has been supposed to have been repeatedly received, some other sever with arterial debility has been mistaken for it, as has probably universally been the case, when the small-pox has been said to have been twice experienced.

M. M. Venefection has been recommended by some writers on the first day, where the inflammation was supposed to be attended with sufficient arterial strength, which might perhaps sometimes happen, as the bubo seems to be a suppuration; but the carbuncle, or anthrax, is a gangrene of the part, and shews the greatest debility of circulation. Whence all the means before enumerated in this genus of diseases to support the powers of life are to be administered. Currents of cold air, cold water,

ice, externally on the hot parts of the skin.

The methods of preventing the spreading of this disease have been much canvassed, and seem to consist in preventing all congregations of the people, as in churches, or play-houses; and to remove the sick into tents, on some airy common, by the side of a river, and supply them with fresh food, both animal and vegetable; with beer and wine, in proper quantities; and to encourage those who can, daily to wash both their clothes and themselves.

The pellis vaccina, or difease amongst the cows, which afflicted this island about half a century ago, seems to have been a contagious

contagious fever, with great arterial debility; as in some of them. in the latter stage of the disease, an emphysema could often be felt in some parts, which evinced a considerable progress of gangrene beneath the skin. In the sensitive inirritated severs of thefe animals, I suppose about fixty grains of opium, with two ounces of extract of oak-bark, every fix hours, would supply them with an efficacious medicine; to which might be added thirty grains of vitriol of iron, if any tendency to bloody urine should appear, to which this animal is liable. The method of preventing the infection from spreading, if it should ever again gain access to this island, would be immediately to obtain an order from government to prevent any cattle from being removed, which were found within five miles of the place supposed to be infected, for a few days; till the certainty of the existence of the pestilence could be ascertained, by a committee of medical people. As foon as this was afcertained, all the cattle within five miles of the place should be immediately slaughtered, and confumed within the circumfcribed district; and their hides put into lime-water before proper inspectors.

14. Pemphigus is a contagious difease, attended with bladdery eruptions, appearing on the second or third day, as large as filberts, which remain many days, and then effuse a thin ichor. It seems to be either of a mild kind, with sensitive fever only, of which I have seen two instances; or with irritated, or with instricted sever; as appears from the observations of M. Salabert. See Medical Comment. By Dr. Duncan, Decad. II. Vol. VI.

15. Varicella. Chicken-pox is accompanied with fenfitive fever, pustules break out after a mild fever, like the small-pox, feldom suppurate, and generally terminate in scales without scars. I once faw a lady who miscarried during this disease, though all her children had it as flightly as usual. It sometimes leaves scars or marks on the skin. This disease has been mistaken for the fmall-pox, and inoculated for it; and then the fmall-pox has been supposed to happen twice to the same person. See Trans. of the College, London. It is probable that the pemphigus and urticaria, as well as this disease, have formerly been diseases of more danger; which the habit of innumerable generations may have rendered mild, and will in process of time annihilate. the fame manner as the fmall-pox, venereal difease, and rickets, feem to become milder or less in quantity every half century. While, at the fame time, it is not improbable, that other new difeafes may arife, and, for a feafon, thin mankind!

16. Urticaria. Nettle-rash begins with mild sensitive sever, which is sometimes scarcely perceptible. Hence this eruption has been thought of two sorts, one with and the other without

fever. On the fecond day red spots, like parts stung with nettles, are feen; which almost vanish during the day, and recur in the evening with the fever, succeeded in a few days by very mi-

nute scales. See Trans. of the College, London.

17. Aphtha. Thrush. It has been doubted, whether aphtha or thrush, which consists of ulcers in the mouth, should be enumerated amongst febrile diseases; and whether these ulcers are always symptomatic, or the consequence rather than the cause of the fevers which attend them. The tongue becomes rather fwelled; its colour and that of the fauces purplish; floughs or ulcers appear first on the throat and edges of the tongue, and at length over the whole mouth. These sloughs are whitish, fometimes distinct, often coalescing, and remain an uncertain time. Cullen. I shall concisely mention four cases of aphtha, but do not pretend to determine whether they were all of them fymptomatic or original diseases.

Aphtha sensitiva. A lady during pregnancy was frequently feized with ulcers on her tongue and cheeks, or other parts of the mouth, without much apparent fever; which continued two or three weeks, and returned almost every month. The thrush in the mouths of young children feems to be a fimilar difease. These ulcers resemble those produced in the sea-scurvy, and have probably for their cause an increased action of the secerning system from increased sensation, with a decreased action of the absorbent system from decreased irritation. See Class I. 2. 1. 14.

taken frequently into the mouth in very small quantity. See Class II. 1. 3. 1.

Aphtha irritata. Inflammatory aphtha. A case of this kind is related under the title of suppurative rheumatism. Class IV. 2. 1. 16.

M. M. Solutions of alum, of blue vitriol. Powder of bark

Aphtha inirritata. Sloughs or ulcers of the mouth, attended with fenfitive fever with great arterial debility. They feem to spread downwards from the throat into the stomach, and probably through the whole intestinal canal, beginning their course with cardialgia, and terminating it with tenefmus; and might

perhaps be called an eryfipelas of this mucous membrane.

M. M. Cool air. A fmall blifter on the back. Bark. Opium in small repeated quantities. Soap neutralizes the gaftric acid without effervescence, and thus relieves the pain of cardialgia, where the stomach is affected. Milk also destroys a part of this acid. Infusion of fage-leaves two ounces, almond-soap from five grains to ten, with fugar and cream, is generally both agreeable and useful to these patients. See I. 2. 4. 5.

Where the stomach may be supposed to be excoriated by poi-

fons containing acid, as fublimate of mercury or arfenic; or if it be otherwise inflamed, or very sensible to the stimulus of the gastric acid; or where it abounds with acid of any kind, as in cardialgia; the exhibition of scap is perhaps a preferable manner of giving alkali than any other, as it decomposes in the stomach without effervescence; while the caustic alkali is too acrid to be administered in such cases, and the mild alkali produces carbonic gas. If a drop of acid of vitriol be put on cap-paper, it will be long before it destroys the paper; but if a drop of mild alkali be added, a sudden effervescence arises, and the paper is instantly destroyed by the escape of the fixed air; in the same manner as lumps of solid lime are broken into powder by the escape of the steam produced from the water, which is poured on them. This shews why a succession of acid and of alkaline caustics sooner destroys a part, than either of them applied separately.

18. Dysenteria. Bloody-flux is attended with fensitive fever, generally with arterial debility; with frequent mucous or bloody stools, which contain contagious matter produced by the membranes of the intestines; the alimentary excrement being never-

thelefs, retained; with griping pains, and tenefmus.

Linneus observed microscopic animals in the stools of dysenteric patients, and concluded from thence that they were the cause of the disease; in the same manner the animalcula, seen by microscopes, in the pustules of the itch, have been supposed to be the cause of those eruptions. See Article IV. 2. 1. 3. These animalcula are nevertheless seen in almost all animal sluids which have for a time stagnated; as in the semen, and in all liquid evacuations from the intestines, as afferted by Busson; who esteems them to be organized beings, though not perfect animals, in his ingenious treatise on generation. Histoire Naturel.

M. M. Emetics. Antimonials. Peruvian bark. Opium and calomel, of each a grain every night. Bolus armenire. Earth of alum. Chalk. Calcined hartshorn. Mucilage. Bee's wax mixed with yolk of egg. Cerated glass of antimony. Warm bath. Flannel clothing next to the skin. Large clysters with opium. With ipecacuanha, with smoke of tobacco? Two dysenteric patients in the same ward, of the infirmary at Edinburgh, quarrelled, and whipped each ther with horsewhips a long time, and were both much better after it, owing perhaps to the exertion of so much of the sensorial power of volition; which, like real infanity, added excitement to the whole system.

The prevention of this contagion must consist principally in ventilation and cleanliness; hence the patients should be removed into cottages distant from each other, or into tents; and

their fæces buried as foon as may be; or conveyed into a running fiream; and themselves should be washed with cold or warm water after every evacuation. For the contagious matter consists in the mucous or purulent discharge from the membrane which lines the intestines; and not from the febrile perspiration, or breath of the patients. For the fever is only the consequence and not the cause of contagion; as appears from Genus the Fifth of this Order, where contagion exists without fever.

19. Gastritis superficialis. Superficial inflammation of the stomach. An erysipelatous inflammation of the stomach is mentioned by Dr. Cullen from his own observations; which is distinguished from the inflammatory gastritis by less pain and sever, and by an erysipelatous redness about the sauces. Does this

disease belong to aphtha?

20. Enteritis superficialis. Superficial inflammation of the bowels is also mentioned by Dr. Cullen, from his own observation, under the name of enteritis erythematica; and is said to be attended with less pain and sever, without vomiting, and with diarrhoea. May not this disease be referred to aphtha, or to dysentery?

Vol. II. E E ORDO

ORDO I.

Increased Sensation.

GENUS IV.

With the Production of new Vessels by internal Membranes or Glands, without Fever.

Where inflammation is produced in a small part, which has not great natural sensibility, the additional sensation does not produce an increased action of the arterial system; that is, the affociated motions which are employed in the circulation of the blood (those for instance of the heart, arteries, glands, capillaries, and their correspondent veins), are not thrown into increased action by so small an addition of the sensorial power of sensation. But when parts which naturally possess more sensibility become inflamed, the quantity of the sensorial power of sensation becomes so much increased, as to affect the affociated motions belonging to the circulation, occasioning them to proceed with greater frequency; that is, a sever is induced. This is well exemplified in the internal and superficial paronychia; one of which is attended with great pain and sever, and the other with little pain and no sever. See Class II. 1. 2. 19. and II. 1. 4. 5.

From hence it appears, that the sensitive fever is an accidental consequence of the topical phlegmon, or inflammation, and not a cause of it; that it is often injurious, but never salutary; and should therefore always be extinguished, as soon as may be, either by the lancet and cathartics, and diluents, and cold air, when it is of the irritated kind; or by the bark, opium, cool air,

and nutrientia, when it is of the inirritated kind.

SPECIES.

1. Ophthalmia superficialis. As the membranes, which cover the eye, are excluded from the air about one third part of the twenty-four hours, and are moistened by perpetual nictitation during the other fixteen, they may be considered as internal membranes; and, from the analogy of their inflammation to that of other internal membranes, it is arranged under this genus; whilst the tonsillitis is esteemed an inflammation of an external membrane, because currents of air are perpetually passing both day and night over the fauces.

The fuperficial ophthalmy has generally been esteemed a

fymptom

fymptom of fcrofula, when it recurs frequently in young perfons; but is probably only a concomitant of that difease, as a fymptom of general debility; ramifications of new red veffels, and of enlarged old ones, are spread over the white part of the eye; and it is attended with less heat, less pain, and less intolerance of light than the ophthalmia interna, described in Class II. 1. 2. 2. It occurs in those of feeble circulation, especially children of a scrofulous tendency, and seems to arise from a previous torpor of the vessels of the tunica albuginea from their being exposed to cold air; and from this torpor being more liable to occur in habits, which are naturally inirritable; and therefore more readily fall into quiescence by a smaller deduction of the stimulus of heat, than would affect stronger or more irritable habits; the confequence of this terpor is increased action, which produces pain in the eye, and that induces inflammation by the acquisition of the additional fensorial power of fensation.

Ophthalmia lymphatica is a kind of anafarca of the tunica adnata; in this the veffels over the felerotica, or white part of the eye, rife confiderably above the cornea, which they furround, are lefs red than in the ophthalmia fuperficialis, and appear to be fwelled by an accumulation of lymph rather than of blood; it is probably owing to the temporary obstruction of a branch of

the lymphatic fystem.

M. M. If the pain be great, venefection by leeches on the temple, or cutting the temporal artery, and one purge with three or four grains of calomel should be premifed. Then the Peruvian bark twice a day. Opium from a quarter to half a grain twice a day, for some weeks. Bathe the eye frequently with cold water alone, or with cold water to a pint of which is added half an ounce of falt. White vitriol, six grains dissolved in one ounce of water; a drop or two to be put between the eyelids twice a day. Take very small electric sparks from the eyes every day for a fortnight. Bathe the whole head with falt and water made warm, every night, for some months. Send such children to a school near the sea, for the convenience of sea bathing, for many months, annually; such schools are to be found in or near Liverpool.

When a child is afflicted with an inflamed eye of this kind, he should always sit with his back to the window or candle; but it is generally not necessary to cover it, or if the uneasy senfation of light makes this proper, the cover should stand off from the eye, so as not much to exclude the cool air from it. As covering an eye unnecessarily is liable to make that eye weaker than the other, from its not being sufficiently used, and thence

to produce a fquinting forever afterwards.

Nevertheless,

Nevertheless, when the pain is great, a poultice must be applied to keep the eyes moift, or a piece of oiled silk bound lightly over them. Or thus, boil an egg till it is hard, cut it longitudinally into two hemispheres, take out the yolk, sew the backs of the two hollow hemispheres of the white to a ribbon, and bind them over the eyes every night on going to bed; which, if nicely fitted on, will keep the eyes moist without any disagreea-

ble pressure. See Class I. 1. 3. 14.

Ophthalmia equina. An inflammation of this kind is liable to affect the eyes of horses; one cause of which is owing to a filly custom of cutting the hair out of horses' ears; by which they are not only liable to take cold at the ear, but grass-seeds are liable to fall into their ears from the high racks in stables; and in both cases the eye becomes inflamed by sympathy. I once directed the temporal artery of a horse to be opened, who had frequent returns of an inflamed eye; and I believed it was of effential service to him; it is probable that the artery was afterwards contracted in the wounded part, and that thence less blood was derived to the eye: the hæmorrhage was stopped by two persons alternately keeping their singers on the orifice, and afterwards by a long bandage of broad tape.

2. Pterigion. Eye-wing. A fpot of inflammation fometimes begins on the infide of the lower eyelid, or on the tunica albuginea, and fpreads an intertexture of red veffels from it, as from a centre, which extend on the white part of the eye, and have the appearance of the wing of a fly, from whence its name.

M. M. Cut the ramifications of vessels again and again, with the point of a lancet, close to the centre of inflammation. Touch them repeatedly with lunar caustic. See Home on the urethra.

Page 101.

Mr. Hadley of Derby procured an ingenious instrument to be made to cut the vessels, which had spread their numerous branches over an opaque cornea, after a violent inflammation; by which they were repeatedly divided, with little pain to the patient, as there was no necessity to hold them by a forceps. The instrument was in the form of a corn-fickle, or the early crescent of the new moon, about an inch in length, the inner edge of the curve was sharp, and the point sine; the back was rounded and smooth, and the other end sixed in an ivory handle. The point of this was suddenly introduced under the branches of the new vessels, which were thus cut upwards, and there was no occasion to hold the eye, or the trunks of the vessels.

3. Tarfitis palpebrarum. Inflammation of the edges of the eyelids. This is a difease of the glands, which produce the hairs of the eyelashes, and is frequently the cause of their falling off.

After this inflammation a hard fear-like ridge is left on the edge of the eyelid, which feratches and inflames the eyeball, and be-

com es a very troublesome disease.

The Turkith ladies are faid to colour the edge of the eyelash with the least antimony in very sine powder, which not only gives lust to the cro, as a diamond set on a black foil, but may prevent extrated as light from being reslected from these edges into the cro, and the core the purpose of the black seathers about the cross of the cyclid seron being instanced by the second the coges of the cyclids from being instanced by the second the coges of the cyclids from being instanced by the second the coges of the cyclids from being instanced by the second the coges of the cyclids from being instanced by the second the coges of the cyclids from being instanced by the second the coges of the cyclids from being instanced by the second the coges of the cyclids from being instanced by the second the coges of the cyclids from the cyclids fr

Burnt alum fixty grains, hog's greafe half an one well rubbed into an ointment to be smeared on them in the last. Columeter frequently in the day. See Class II.

on the cheer of the eye-lids, or in the loofe skin of them, and is cometanes very slow either in coming to suppuration or in dispring. The skin beneath the lower eyelid is the most freedent to of this tumor, which sometimes never suppurates at all, out becomes an encysted tumor: for as this skin is very loofe for the purpose of admitting great motion to the eyelid, the absorbent power of the veins seems particularly weak in this part; whence when any person is weakened by fatigue or otherwise, a darker shade of colour is seen beneath the eyes; which is owing to a less energetic action of the absorbent terminations of the veins, whence the currents of dark or venons blood are delayed in them. This dark shade beneath the eyes, when it is permanent, is a symptom of habitual debility, or inirritability of the circulating system. See Class I. 2. 2. 2.

M. M. Smear the tumors with mercurial ointment, moisten them frequently with ether. To promote their suppuration they may be wounded with a lancet, or slit down the middle, or they

may be cut out. A caustic leaves a large scar.

5. Paronychia superficialis. Whitlow. An inflammation about the roots of the nail beneath the skin, which suppurates without sever, and sometimes destroys the nail; which is, however, gradually reproduced. This kind of abscess, though not itself dangerous, has given opportunity for the ineculation of venereal matter in the hands of accoucheurs, and of putrid matter from the diffection of diseased bodies; and has thus been the cause of disease and death. When putrid matter has been

thus

thus absorbed from a dead body, a livid line from the finger to the swelled gland in the axillais said to be visible; which shews the inflammation of the absorbent vessel along its whole course to the lymphatic gland; and death has generally been the consequence.

M. M. In the common paronychia a poultice is generally fufficient. In the absorption of putrid matter rub the whole hand and arm with mercurial ointment three or four times a day, or perpetually. Could the swelled axillary gland be exsected? In the absorption of veneral matter the usual methods of cure in syphilis must be administered, as in Class II. 1. 5. 1.

6. Guita resea. The rosy drop on the face is of three kinds. First the gutta resea hepatica, or the red pimples on the faces of drunkards, which are probably a kind of crisis, or vicarious inflammation, which succeeds, or prevents, a torpor of the membranes of the liver. This and the succeeding species properly

belong to Class IV. 1. 2. 14.

Secondly, the pimpled face, in consequence of drinking cold water, or eating cold turnips, of other insipid food, when much heated with exercise; which probably arises from the sympathy between the skin of the face and the stomach; and may be called the gutta rosea stomatica. Which is distinguished from the former by the habits of the patient in respect to drinking; by the colour of the eruptions being less deep; and by the patient continuing generally to be troubled with some degree of apepsia. See Class I. 3. 1. 3. I knew a lady who had long been afflicted with pain about the region of the stomach; and, on drinking half a pint of vinegar, as a medicine, she had a breaking out commenced on her face; which remained, and she became free from the pain about the stomach. Was this a stomachic, or an hepatic disease?

Thirdly, there is a red face, which confifts of fmaller pimples than those above mentioned; and which is less liable to suppurate; and which seems to be hereditary, or at least has no apparent cause like those above mentioned; which may be termed

gutta rosea hereditaria, or puncta rosea.

Mrs. S. had a pimpled face, which I believe arose from potation of ale. She applied alum in a poultice to it, and had soon a paralytic stroke, which disabled her on one side, and terminated in her death.

Mrs. L. had a red pimpled face, which feemed to have been derived from her mother, who had probably acquired it by vinous potation; the applied a quack remedy to it, which I believe was a folution of lead, and was feized with epileptic fits, which terminated in palfy, and destroyed her. This shews the danger of using white paint on the face, which is called bifmuth, but is

in reality white lead or cerussa; and if it be bismuth, it may be

equally deleterious.

Mr. Y — had acquired the gutta rosea on his nose, and applied a faturnine solution on it for a few nights, and was then seized with paralysis on one side of his face; which however he gradually recovered, and has since acquired the gutta rosea on

other parts of his face.

These fatal effects were probably caused by the disagreeable fensation of an inflamed liver, which used before to be relieved by the sympathetic action and consequent inflammation of the skin of the face, which was now prevented by the stronger stimulus of the application of calx of lead. The manner in which disagreeable sensations induce epilepsy and palsy is treated of in Class III. In some cases where habitual discharges, or eruptions, or ulcers, are stopped, a torpor of the system may follow, owing to the want of the accustomed quantity of sensation or irritation. See Class I. 1. 2. 9. and II. 1. 5. 6. In both these situations some other stimulus should be used to supply the place of that which is taken away; which may either be perpetual, as an issue; or periodical, as a cathartic repeated once a fortnight or month.

Miss W. an elegant young lady, of about twenty, applied a mercurial lotion to her face, which was covered with very small red points (which seemed to have been not acquired by any known or avoidable means); she was seized with instammation of her liver, and, after repeated bleeding and cathartics, recovered;

and in a few weeks the eruption appeared as before.

M. M. Five grains of calomel once a month, with a cathartic, five grains of rhubarb and a quarter of a grain of emetic tartar every night for many weeks. With this preparation mercurial plasters, made without turpentine, and applied every night, and taken off every morning, will sometimes succeed, and may be used with safety. But blistering the sace all over the eruption, beginning with a part, succeeds better than any other means, as I have more than once experienced.—Something like this is mentioned in the Letters of Lady Mary Wortley Montague, who blistered her sace with balsam of Mecca.

Mrs. F. had for many years had a difagreeably looking eruption on her chin. After a cathartic with calomel, she was advised to blifter her whole chin; on the healing of the blifter a few eruptions again appeared, which ceased on the application of a second blifter. She took rhubarb five grains, and emetic

tartar a quarter of a grain every night for many weeks.

Miss L. a young lady, about eighteen, had tried variety of advice, for pimples over the greatest part of her face, in vain. She

took the above medicines internally, and bliftered her face by degrees all over, and became quite beautiful. A fpot or two now and then appeared, and on this account she frequently slept with parts of her face covered with mercurial plaster, made without turpentine, which was held on by a pasteboard mask, and taken off in the mornings; if any part of the plaster adhered, a little butter or oil destroyed the adhesion. If there be turpentine, or any other native balsam, mixed with the mercurial plaster, it is very liable much to inslame the face (I suppose like the balsam of Mecca); but if a small quantity of flour of brimstone be added, I believe it will readily mix. As a mercurial ointment is said to be quickly made by adding only six grains of flour of sulphur to fix drachms of mercury, and two ounces of hog's grease.

7. Odontitis. Inflammatory tooth-ach is occasioned by inflammation of the membranes of the tooth, or a caries of the bone itself. The gum sometimes suppurates, otherwise a swelling of the cheek succeeds by affociation, and thus the violence of the pain in the membranes of the tooth is relieved, and frequently cured; and when this happens the disease properly belongs to Class IV. as it so far resembles the translations of mor-

bid actions in the gout and rheumatism.

At other times the tooth dies without caries, especially in people about fixty years of age, or before; and then it stimulates its involving membrane, like any other extraneous substance. The membrane then becomes inflamed and thickened, occasioning some pain, and the tooth rises upwards above the rest, and is gradually pushed out whole and undecayed; on its rising up a pus-like mucus is seen discharged from the gum which surrounds it; and the gum seems to have left the tooth, as the sange or

roots of it are in part naked.

M. M. Where the tooth is found it can only be faved by evacuations, by venefection, and a cathartic; and after its operation two grains of opium. A blifter may also be used behind the ear, and ether applied to the cheek externally. In slighter cases two grains of opium with or without as much camphor may be held in the mouth, and suffered to dissolve near the affected tooth, and be gradually swallowed. See Class I. 2. 4.

12. Odontalgia may be distinguished from otitis by the application of cold water to the affected tooth; for as the pain of common tooth-ach is owing to torpor, whatever decreases stimulus adds to the torpor and consequent pain; whereas the pain of an inflamed tooth, being caused by the increased action of the membranes of it, is in some measure alleviated by the application of cold.

8. Otitis. Inflammation and confequent suppuration of some membranes

membranes of the internal ear frequently occur in children, who sleep in cold rooms, or near a cold wall, without a night-cap. If the bones are affected, they come out in a long process of time, and the child remains deaf of that ear. But in this case there is generally a sever attends this inflammation; and it then belongs to another genus.

M. M. A warmer night-cap. Warmish water should be gently syringed into the ear, to keep it clean, twice a day; and if it does not heal in a week, a little spirit of wine should be added; first about a fourth part, and it should be gradually increased to half rectified spirit and half water: if it continues long to discharge matter with a very putrid smell, the bones are injured, and will in time find their exit; during which time the ear should be kept clean, by filling it with a weaker mixture of spirit of wine and water, or a solution of alum in water; which may be poured into the ear, as the head is inclined, and shook out again by turning the head, two or three times morning and evening. See Class II. 1. 4. 10.

9. Fiftula lacrymalis. The lacrymal fack, with its puncta lacrymalia and nafal duct, are liable to be destroyed by suppuration without fever; the tears then run over the eyelids, and instance the edges of them and the cheeks, by their perpetual moisture

and faline acrimony.

M. M. By a nice furgical operation, a new aperture is to be made from the internal corner of the eye into the nostril, and a filver tube introduced, which supplies the defect by admitting the tears to pass again into the nostril. See Mélanges de Chirurgie, par M. Pouteau; who thinks he has improved this operation.

10. Fifula in ano. A mucous discharge from the anus, called by some white piles, or matter from a suppurated pile, has been mistaken for the matter from a concealed sistula. A bit of cotton-wool applied to the fundament to receive the matter, and renewed twice a day for a week or two, should always be used before examination with the probe. The probe of an unskilful empyric sometimes does more harm in the loose cellular membrane of these parts than the original ulcer, by making a sistula he did not find. The cure of a sistula in ano, of those who have been much addicted to drinking spirituous liquor, or who have a tendency to pulmonary consumption, is frequently of dangerous consequence, and is succeeded by ulcers of the lungs, and death.

M. M. Ward's paste, or 20 black pepper-corns taken after each meal twice a day; the pepper-corns should be cut each into two or three pieces. The late Dr. Munro, of Edinburgh, Vol. II.

afferted, in his lectures, that he had known a fiftula in ano cured by injecting first a mixture of rectified spirit of wine and water; and, by gradually increasing the strength of it, till the patient could bear rectified spirit alone; by the daily use of which, at length, the fides of the fiftula became callous, and ceafed to difcharge, though the cavity was left. A French furgeon has lately affirmed, that a wire of lead put in at the external opening of the ulcer, and brought through the rectum, and twifted together, will gradually wear itself through the gut, and thus effect a cure without much pain. The ends of the leaden wire must be twisted more and more as it becomes loose. Or, lastly, it must be laid open by the knife.

11. Fistula urethra. Where a stricture of the urethra exists. from whatever cause, the patient, in forcing the stream of urine through the stricture, distends the urethra behind it; which, after a time, is liable to burst, and to become perforated; and some of the urine is pushed into the cellular membrane, occafioning fiftulas, which fometimes have large furfaces producing much matter, which is pressed out at the time of making water, and has been mistaken for a catarrh of the bladder; these fiftulas fometimes acquire an external opening in the perinæum, and

part of the urine is discharged that way.

Can this matter be diftinguished from mucus of the bladder by

the criterion delivered in Class II. 1. 6. 6. ?

M. M. The perpetual use of bougies, either of catgut or of caoutchouc. The latter may be had at No. 37, Red-lion-street, Holborn, London. The former are easily made, by moistening the catgut, and keeping it stretched till dry, and then rounding one end with a pen-knife. The use of a warm bath every day for near an hour, at the heat of 04 or 06 degrees, for two or three months, I knew to be uncommonly successful in one case; the extensive fiftulas completely healing. The patient should introduce a bougie always before he makes water, and endeavour

to make it as flowly as possible. See Class I. 2. 3. 24

12. Hepatitis chronica. Chronical inflammation of the liver. A collection of matter in the liver has frequently been found on diffection, which was not suspected in the living subject. Though there may have been no certain figns of fuch a collection of matter, owing to the infensibility of the internal parts of this viscus; which has thus neither been attended with pain, nor induced any fever; yet there may be in some cases reason to sufpect the existence of such an abscess; either from a sense of sulness in the right hypochondre, or from transient pains sometimes felt there, or from pain on pressure, or from lying on the left side, and sometimes from a degree of sensitive fever attending it.

Dr. Saunders

Dr. Saunders suspects the acute hepatitis to exist in the inflammation of the hepatic artery, and the chronical one in that of the vena portarum. Treatise on the Liver. Robinsons. London.

13. Scrofula suppurans. Suppurating scrofula. The indolent tumors of the lymphatic glands are liable, after a long time, to regain their sensibility; and then, owing to their former torpor, an increased action of the vessels, beyond what is natural, with infiammation, is the consequence of their new life, and suppuration succeeds. This cure of scrofula generally happens about puberty, when a new energy pervades the whole system, and unfolds the glands and organs of reproduction.

M. M. See Class I. 2. 3. 21. Where for fulous ulcers about the neck are difficult to heal, Dr. Beddoes was informed, in Ireland, that an empyric had had some success by inflaming them by an application of wood forrel, oxalis aceto sella, the leaves of which are bruised in a mortar, and applied on the ulcers for two or three days, and then some more lenient application is used.

A poor boy, about twelve years old, had a large fcrofulous ulcer on one fide of the cheft beneath the clavicle, and another under his jaw; he was directed, about three weeks ago, to procure a pound of dry oak-bark from the tanners, and to reduce it to fine powder, and to add to it one ounce of white lead in fine powder, and to cover the ulcers daily with it, keeping it on by brown paper and a bandage. He came to me a few minutes ago, to fhew me that both the ulcers are quite healed. The conftant application of linen rags, moistened with a folution of an ounce of fugar of lead in a pint of water, I think I have feen equally efficacious.

Small doses internally of a solution of arsenic have been said to contribute to cure these ulcers. I should recommend from one drop to five of a saturated decoction of arsenic, as directed in Mat. Med. Art. IV. 2. 6. 8. for children, twice or thrice a day, according to their age, and from five to ten to grown perfons, diminishing the quantity if it affects the bowels. Tinc-

ture of Digitalis is recommended in Class I. 2. 3. 21.

14. Scorbutus fuppurans. In the fea-scurvy there exists an inactivity of venous absorption, whence vibices and petechiæ, and sometimes ulcers. As the column of blood pressing on the origins of the veins of the lower extremities, when the body is erect, opposes the ascent of the blood in them, they are more frequently liable to become enlarged, and to produce varixes, or vibices, or, lastly, ulcers about the legs, than on the upper parts of the body. The exposure to cold is believed to be another cause of ulcers on the extremities; as happens to many of the

poor in winter, at Lisbon, who sleep in the open air, without stockings, on the steps of their churches or palaces. See Class I. 2. 1. 15.

M. M. A bandage fpread with plaster to cover the whole limb tight. Rags dipped in a solution of sugar of lead. A warm stannel stocking or roller. White lead and oak-bark, both in fine powder. Horizontal rest. An ingenious treatise on the use of bandage, in the cure of ulcers, has lately been published by Mr. Baynton, of Bristol; and another, on the same subject, by Mr. Whately, of London, who succeeds without using

plaster on the bandage.

of no great extent or fensibility, it is, after a long period of time, liable to suppurate without inducing fever, like the indolent tumors of the conglobate or lymphatic glands above mentioned; whence collections of matter are often found after death, both in men and other animals; as in the livers of swine, which have been fed with the grounds of fermented mixtures in the distilleries. Another termination of scirrhus is in cancer, as described below. See Class I. 2. 3. 22.

16. Carcinoma. Cancer. When a fcirrhous tumor regains its fensibility by nature, or by any accidental hurt, new vessels shoot amongst the yet insensible parts of it, and a new secretion takes place of a very injurious material. This cancerous matter is absorbed, and induces swelling of the neighbouring lymphatic glands; which also become scirrhous, and afterwards

cancerous.

This cancerous matter does not feem to acquire its malignant or contagious quality, till the cancer becomes an open ulcer; and the matter fecreted in it is thus exposed to the air. Then it evidently becomes contagious, because it not only produces hectic fever, like common matter in ulcers open to the air, but it also, as it becomes absorbed, swells the lymphatic glands in its vicinity; as those of the axilla, when the open cancer is on the breast. See Class II. 1. 3.

Hence exsection before the cancer is open is generally a cure; but after the matter has been exposed to the air, it is seldom of service; as the neighbouring lymphatic glands are already infected. I have observed some of these patients after the operation to have had diseased livers, which might either have previously existed, or have been produced by the sear or anxiety at-

tending the operation.

Erosion with arsenic, after the cancer is become an open ulcer, has generally no better effect than exsection, but has been successful before ulceration. The best manner of using arsenic, is by mixing one grain with a drachm of lapis calminaris, and strewing on the cancer some of the powder every day, till the

whole is destroyed.

Cancers on the face are faid to arise from the periosteum, and that, unless this be destroyed by the knife, or by caustics, the cancer certainly recurs. After the cancer becomes an open ulcer of some extent, a purulent sever supervenes, as from other open ulcers, and gradually destroys the patient. See Class II. 1. 6. 13.

Two very interesting cases have been lately published by Dr. Ewart, of Bath, in which carbonic acid gas, or fixed air, was kept constantly in contact with the open cancerous ulcers of the breast; which then healed like other common ulcers. This is rather to be ascribed to the exclusion of oxygen, than to any specific virtue in the carbonic acid. As in common ulcers the matter does not induce healtic fever, till it has been exposed

to the air, and then probably united with oxygen.

The manner of applying the fixed air, is by including the cancer in one half, or hemisphere, of a large bladder; the edges are made to adhere to the skin by adhesive plaster, or perhaps a mixture of one part of honey with about twenty parts of carpenter's glue might better suit some tender skins. The bladder is then kept constantly silled with carbonic acid gas, by means of a pipe in the neck of it; and the matter let out at a small aperture beneath.

M. M. Where extirpation is not advisable, as in most open cancers of the breast, keep the ulcer carefully from the air, either by applying carbonic acid gas, as above; or by covesing it with charcoal in powder, and a double oiled silk. The charcoal-powder should be renewed once in two or three days, and at those times it should be pushed off by fresh charcoal-powder on lint, so as not for a moment to expose it to the air. The charcoal should be fresh taken from the fire, and powdered very fine as soon as cool, and kept in a bottle to be as little exposed to the air as possible.

The tumor should be suspended by a fash or soft cushion, so as to keep it as easy as possible night and day, and should be kept neither too warm nor too cold, as both extremes are injurious.

Internally, fix grains of rhubarb every night, for many months, and to drink nothing stronger than common weak small beer, consisting of three strike of malt to the hogshead, or wine diluted with thrice its quantity of water.

If caustics cannot be applied so as to destroy the whole, even before ulceration, I suspect that they aggravate the evil, and sooner destroy the patient; as, I was well informed, occurred

to a quack who was for a time much reforted to, in this part of the country.

Another method of using charcoal-powder is by mixing it with boiled oil, to the consistence of common paint; and to soak a piece of slannel with this, and cover the ulcer; and daily to shove or thrust this off by applying the edge of another piece of slannel, soaked with the oil and charcoal, to the edge of that upon the ulcer, so as to change them without the possibility of let-

ting any air come into contact with the cancerous fore.

17. Arthrocele. Swelling of the joints feems to have its remote cause in the softness of the bones, for they could not swell unless they were previously softened, see Class 1. 2. 2. 12. The epiphyfes, or ends of the bones, being naturally of a loofer texture, are most liable to this disease, and perhaps the cartilages and capfular ligaments may also become inflamed and swelled along with the heads of the bones. This malady is liable to distort the fingers and knees, and is usually called gout or rheumatism; the former of which is liable to difable the fingers by chalk-stones, and thence to have fomewhat a fimilar appearance. But the arthrocele, or fwelling of the joints, affects people who have not been intemperate in the use of fermented or spirituous liquors; or who have not previously had a regular gout in their feet; and in both these circumstances differs from the gout. Nor does it accord with the inflammatory rheumatism, as it is not attended with feyer, and because the tumors of the joints never entirely fubfide. The pain or fensibility, which the bones acquire when they are inflamed, may be owing to the new veffels, which shoot in them in their foft state, as well as to the distention of the old ones.

M. M. Half a grain of opium twice a day, gradually increased to a grain, but not further, for many months. Thirty grains of powder of bark twice a day for many months. Ten grains of bone-ashes, or calcined hartshorn, twice a day, with decoction

of madder? Soda phosphorata?

18. Arthropuosis. Joint-evil. This differs from the former, as that never suppurates; these ulcers of the joints are generally esteemed to arise from scrosula; but as scrosula is a disease of the lymphatic or absorbent system, and this consists in the suppuration of the membranes, or glands, or cartilages about the joints, there does not seem a sufficient analogy to authorize their arrangement under the same name.

The white fwelling of the knee, when it suppurates, comes under this species, with variety of other ulcers, attended with cari-

ous bones.

19. Caries offium, or Necrolis offium. A caries of the bones may

may be termed a suppuration of them; it differs from the above, as it generally is occasioned by some external injury, as in decaying teeth; or by veneral virus, as in nodes on the tibia; or by other matter derived to the bone in malignant severs; and is not confined to the ends of them.

The feparation of the dead bone from the living is a work of fome time. See Sect. XXXIII. 3. 1. A new and able work on the necrofis of bones is published by I. Russel, Edinburgh; London, Robinsons. And another by I. P. Weidmann, de Necrosi Ossium at Francfort; Boosey, London; which is also a valuable work.

M. M. When this difease is not formed in syphilis, or by metastasis in sever, but is simply an inflammation of the periosteum, or of the solid bone, or of its medullary cells, the method of cure should consist in evacuations by bleeding and cathartics, and by leeches applied to the painful or tumid parts; and afterwards by taking inwardly soda phosphorata and a decoction of rubia tinctorum, madder-root; as the former is believed to give solidity to bones, and the latter, as it colours the bones of young or growing animals, is known to be carried thither during their softer or more sensitive state, and may be therefore worth a trial. See Innutritio ofsium. Class I. 2. 2. 14.

ORDO I.

Increased Sensation.

GENUS V.

With the Production of new Vessels by external Membranes of Glands, without Fever.

The ulcers, or eruptions, which are formed on the external fkin, or on the mouth or throat, or on the air-cells of the lungs, or on the intestines, all of which are more or less exposed to the contact of the atmospheric air, which we breathe, and which in some proportion we swallow with our food and saliva; or to the contact of the instammable air, or hydrogen, which is set at liberty by the putresying aliment in the intestines, or by putresying matter in large abscesses; all of them produce contagious matter; which, on being inoculated into the skin of another person, will produce sever, or a similar disease.

In fome cases even the matter formed beneath the skin becomes in some degree contagious, at least so much so as to produce sever of the hectic or malignant kind, as soon as it has pierced through the skin, and has thus gained access to some kind of air; as the fresh pus of a common abscess; or the putrid pus of an abscess which has been long confined; or of cancerous

ulcers.

From this analogy there is reason to suspect that the matter of all contagious diseases, whether with or without sever, is not infectious till it has acquired something from the air; which, by oxygenating the secreted matter, may probably produce a new acid. And, secondly, that in hectic sever a part of the purulent matter is absorbed; or acts on the surface of the ulcer; as variolous matter affects the inoculated part of the arm. And that hectic sever is therefore caused by the matter of an open ulcer; and not by the sensation in the ulcer independent of the aerated pus, which lies on it Which may account for the venereal matter from buboes not giving the insection, according to the experiments of the late Mr. Hunter, and for some other phenomena of contagion. See Variola discreta, Class II. 1. 3.9.

SPECIES.

1. Gonorrhæa venerea. A pus-like contagious material discharged from the urethra after impure cohabitation, with smart-

ing or heat on making water; which begins at the external extremity of the urethra, to which the contagious matter is applied, and where it has access to the air; which probably height-

ensits acrimony.

M. M. In this state of the venereal disease, once venesection, with mild cathartics of senna and manna, with mucilage, as almond emulsion, and gum arabic, taken for two or three weeks, absolve the cure. Is camphor of use to relieve the ardor uring? Do balfams increase or lessen the heat of urine? Neutral salts certainly increase the smarting in making water, by increasing the acrimony of the urine.

Can the dicharge from the urethra be foon stopped by faturnine injections, or mercurial ones, or with folution of blue vitriol, at first very dilute, and gradually made stronger? And at the same time, lest the syphilis, or general disease, should supervene, the patient might take a quarter of a grain of corrosive sublimate of

mercury twice a day, as directed below?

There is a curious paper by Mr. Addington, of West Bromage, in the Contributions of Medical Knowledge, published by Dr. Beddoes, on the cure of gonorrhea virulenta, by large doses of corrosive sublimate of mercury, hydrargyrus muriatus. Three grains of corrosive sublimate of mercury are dissolved in one ounce of rectified spirit of wine. Half of this mixture is taken undiluted at going to bed; it produces a copious salivation for an hour and a half, or longer, during which the patient spits a quart. Some Glauber's salts are to be taken on the second day after this operation, and on the evening of that day he is to repeat the draught, and the salts on the day but one following. And Mr. Addington witnessed that three or four such doses frequently cured a venereal gonorrhea in so short a time, without any disagreeable consequence, and was informed that hundreds had been cured by it.

The probable mode of action of this medicine is owing to the confent of parts between the throat and the urethra, of which many inftances are given in Class IV. 1. 2. 7. on Hydrophobia. Mr. Wright, an elderly furgeon in Derby, thirty years ago, affured me that he had frequently given half a drachm of corrosive sublimate as an emetic, without any inconvenience to the patient; and that it was the famous emetic of a celebrated empyric, and

had been faid to do wonders.

Might not this dose of one grain and a half, dissolved in half an ounce of rectified spirit, be given repeatedly, with prospect of advantage, in Hydrophobia? And perhaps, in an adapted strength and quantity, in Hydrocephalus? If in Croup, Peripaeumonia trachealis?

Vol. II. G G 2. Syphilis.

2. Syphilis. Venereal disease. The contagion shews itself in ulcers on the part first inoculated, as chances; ulcers on the tonsils succeed, with eruption on the skin, especially about the roots of the hair; afterwards on other parts of the skin, terminating in dry scabs; and, lastly, with pain and swelling of the bones.

The corona veneris, or crown of Venus, confifts of the eruptions at the roots of the hair appearing most round the forehead; which is occasioned by this part being more exposed to the air; which we observed, at the beginning of this genus, either produces or increases the virulence of contagious matter. But it is disficult to conceive, from this history, why the throat should be first affected; as it cannot be supposed, that the disease is so often taken by the saliva, like the small-pox, though this may sometimes occur; perhaps very often. The connection between the genitals in men and the throat, is treated of in Class IV. 1. 2. 7. Hydrophobia.

M. M. A quarter of a grain of corrolive fublimate of mercury, taken thrice a day for five or fix weeks, made into a pill with bread-crumbs, or dissolved in a spoonful of brandy and water, is a very efficacious and almost certain cure. When it does not succeed, it is owing either to the drug being bad, or to its having precipitated from the brandy, or from its being spoiled in the pill by long keeping. Opium contributes much to expedite the cure, both of the simple genorrhæa and of venereal ulcers, by increasing absorption both from the mucous

membrane and from the furface of ulcers. A quarter of a grain, or half a grain, may be given with every dofe of the fublimate.

Nitrous acid has been lately strongly recommended, by Mr. Scott, in venereal cases; from an idea that the oxygen, which it consists of in part, is loosely combined, and may be separable in the animal system; and that it may be the oxygen, only, which exists loosely in mercurial calces or oxydes, that acts so successfully, when mercurials are exhibited. Some successful exhibitions of this acid in venereal cases are published; the dose is one drachm and a half, or two drachms, of the strong nitric acid mixed in two pounds of water, to be drunk daily at repeated intervals. Mr. Scott has since used the nitrous acid much diluted with water externally as a warm bath, either partially or generally, with great success, at Bombay, in venereal cases. See Article II. 2. 4. and IV. 2. 7. 1. in the Materia Medica.

It has been now used in this country with success by some, and without success by others, and may perhaps affift the use of mercurials as well as opium in the cure of veneral ulcers; but

should not yet be folcly depended upon.

2. Lepra. Leprofy. Leprofy of the Greeks. The skin is rough with white branny scales, which are full of chinks; often moitt beneath, and itching. The scales on the head or arms of fome drinking people are a difease of this kind. The perspirable matter deligned for the purpose of lubricating the external skin is fecreted in this disease in a too viscid state, owing to the inflammation of the subcutaneous vessels; and, as the absorbents act too strongly at the same time, a viscid mucus is left adhering to the furface of the skin.

In the leprofy of the Jews, described in the thirteenth and fourteenth chapters of Leviticus, the depression of the sore beneath the furface of the skin, and the hairs in it becoming white, seem to have been the principal circumstances, which the priest was directed to attend to for the purpose of ascertaining the discafe.

M. M. Essence of antimony, from 20 drops to 100, twice or thrice a day, with half a pint of decoction of elm-bark; or of malt-tea; or tincture of cantharides, from 20 to 60 drops, four times a day; or fublimate of mercury, with much diluting fluid. Acid of vitriol? Perhaps the cure chiefly depends on much dilution with water, from two to four pints a day, in which elm-bark, or pine-buds, or juniper-tops, may be boiled. Bath or Buxton water drunk in large quantities. Warm bath. Oil-skin bound on the part to confine the perspirable matter. Ointment of tar and fuet; or poultice for two or three days, and then cerate with lapis calaminaris. Diet of rainus and bread. Abstinence from wine, beer, and all spirits, is indispensably neceffary to the cure.

4. Elephantiasis: Leprofy of the Arabs. A contagious difcafe; the skin is thickened, wrinkled, rough, unctuous, destitute of hair, without any fensation of touch in the extremities of the limbs; the face deformed with tubercles; the voice hoarfe,

and with a nafal tone. Cullen.

5. Framboefia. Yaws is faid to be contagious and hereditary. It principally affects the negroes in the West Indies. Edinb.

Eslays, Vol. VI.

6. Pfora. Itch. A contagious prurient eruption. There are two kinds of itch: that which appears between the fingers and under the joints of the knees and elbows; and that which feldom is feen in these places, but all over the other parts of the body. The latter is feldom thought to be the itch, as it does not easily infect even a bed-fellow, and resists the usual means of cure by brimstone.

If the itch be cured too hastily, by rubbing mercurial or arfenical preparations over the whole body, or on too great a part

Class II. r. c. 6.

of it, many bad symptoms are produced; as weakness of digeftion, with pale bloated countenance, and tendency to dropfy. I have twice feen St. Vitus's dance occur, from the use of a mercurial girdle; and once a fwelled liver. I have also feen a fwelled spleen and swelled legs from the external use of arsenic in the cure of the itch. And very numerous and large phlegmons commonly fucceed the too hafty cure of it by other means.

There does not appear a frict analogy between the hafty cure of the itch, and the retrocession of the pustules in the secondary fever of the fmall-pox; because in that the absorption of the matter is evinced by the fwelling of the face and hands, as the pustules recede, as explained in Class II. 1. 3. 9. Variola discreta. And a fever is produced by this absorption; neither of which happen, when the pultules of the itch are destroyed by

mercury or arfenic.

Nor can these inconveniences, which occur on the too hasty cure of the itch, be explained by those which follow the cure of fome kinds of gutta rosea, Class II. 1.4. 6. as in those the eruptions on the face were an affociated disease with inflammation. of the liver or stomach, which they were accustomed to relieve; whereas the itch is not known to have had any previous catena-

tion with other diseases.

In the itch there exists not only great irritation in the production of the pustules, but great sensation is caused by their acrimony afterwards; infomuch that the pain of itching without the interrupted imarting occasioned by scratching, would be intolerable. This great excitement of the two fenforial powers of irritation and fensation is so great, when the pustules are diffused over the whole furface of the body, that a torpor fucceeds the fudden ceasing of it; which affects those parts of the system which were most catenated with the new motions of the skin, as the stomach, whence indigest on and flatulency; or which are generally most liable to fall into torpor, as the numerous glands, which form the liver. Whence the difeases consequent to the hasty cure of the itch are diseases of debility, as tumid viscera, cadematous fwellings, and St. Vitus's dance, which is a debility of affociation. In the fame manner indigestion, with green evacuations, are faid to follow an injudicious application of ceruffa to stop too hastily the exsudation behind the ears of children, Class I. 1. 2. 9. And dropfies are liable to fucceed the cure of old ulcers of the legs, which have long stimulated the fustem.

M. M. The fize of a large pea, of an ointment confifting of one part of white precipitate of mercury, to fix parts of hog's lard well triturated together, to be rubbed on a part of the body

every night, and washed off with soap and water next morning. till every part is cleared; with lac fulphuris twenty grains to be taken every morning inwardly. Warm faline bath, with white vitriol in it. Flowers of fulphur mixed with thick gruel, or with hog's fat. With either of which the body may be smeared all over.

Mr. Grille fays, that those who get manganese from its mines are not subject to the itch; and that he found an ointment, composed of fix parts of finely levigated manganese and of fixteen parts of lard, a more efficacious remedy for the itch than those in common use. Parmentier.

7. Pfora ebriorum. Elderly people, who have been much addicted to spirituous drinks, as beer, wine, or alcohol, are liable to an eruption all over their bodies; which is attended with very afflicting itching, and which they probably propagate from one part of their bodies to another with their own nails by fcratching themselves. I saw fatal effects in one such patient, by a too extensive use of a solution of lead; the eruption disappeared, he became dropfical, and died; I suppose from the too fuddenly ceasing of the great stimulus caused by the eruptions over the whole skin, as in the preceding article.

M. M. The patient should gradually accustom himself to half his usual quantity of vinous potation. The warm bath, with one pound of falt to every three gallons. Mercurial ointments on fmall parts of the skin at a time. A grain of opium at night in-

flead of the usual potation of wine or beer.

8. Herpes. Herpes confifts of gregarious spreading excoriations, which are succeeded by branny scales or scabs. In this disease there appears to be a deficient absorption of the subcutaneous mucus, as well as inflammation and increased secretion of it. For the fluid not only excoriates the parts in its vicinity by its acrimony, but is very faline to the taste, as some of these patients have affured me; I believe this kind of eruption, as well as the tinea, and perhaps all other cutaneous eruption, is liable to be inoculated in other parts of the body by the finger-nails of the patients in scratching themselves.

It is liable to affect the hands, and to return at distant periods; and is probably a fecondary difease, as well as the zona ignea, or

thingles, described below.

M. M. Poultice the eruption with bread and milk, or raw carrots grated, for two or three whole days, to dilute or receive the discharged fluid, and abate the inflammation; then cover the parts with fresh cerate mixed with lapis calaminaris. On the parts not excoriated mercurial ointment, made of one part of white calx of mercury and fix of hog's fat. Internally, after vene-

section,

fection, gentle repeated catharties. Lastly, the bark. Acid of vitriol. Bolus Armenie, or testacea. Antimonials. Decoction of interior bark of elm.

9. Zona ignea. Shingles. This eruption has been thought a fpecies of herpes by some writers, and by others a species of erysipelas. Yellow or livid vesicles appear, producing a corrosive ichor, which is sometimes attended with a degree of fever. It is faid to infest sometimes the thorax and ribs, but its most general fituation is on the small of the back, over one kidney, extend-

ing forward over the course of one of the ureters.

There is reason to suspect, that this also is a secondary or sympathetic disease, as well as the preceding one; but suture observations are required, before it can be removed to the fourth class, or diseases of association. In three patients I have been induced to believe, that the eruption on the loins was a translation of instammation from the external membrane of the kidney to the skin. They had, for a day or two before the appearance of the eruption, complained of a dull pain on the region of one kidney, but without vomiting; by which it was distinguished from nephritis interna, or gravel; and without pain down the outside of the thigh, by which it was distinguished from sciatica. In other situations the shingles may sympathize with other internal membranes, as in a case published by Dr. Russel (De Tabe Glandulari), where the retrocession of the shingles was succeeded by a serious dyspnæx.

M. M. Venefection, if the pulse is strong. Calomel three or four grains, very mild repeated cathartics. Poultice for a few days, then cerate of lapis calaminaris, as in herpes. A grain of emetic tartar dissolved in a pint of water, and taken so as to empty the stomach and intestines, is said much to hasten the cure; compresses soaked in a faturnine solution are recommended externally on the eruption; and cerate where there are ulcerations. Defanet's Surgical Journal, Vol. II. p. 378. If this be a vicarious disease, it should continue half a lunation; lest, on its ceasing, the bad habits of motion of the primary disease should not have been so perfectly dissevered, but that they may recur.

10. Annulus repens. Ring-worm. A prurient eruption formed in a circle, affecting children, and would feem to be the work of infects, according to the theory of Linnaus, who afcribes the itch and dyfentery to microscopic animalcula. These animalcula are probably the effect, and not the cause, of these eruptions; as they are to be seen in all putrescent animal sluids. The annular propagation of the ring-worm, and its continuing to enlarge its periphery, is well accounted for by the acrimony of the ichor or saline sluid eroding the skin in its vicinity.

M. M. Cover

M. M. Cover the eruption daily with ink. With white mercurial ointment, as described above in herpes. With solution of white vitriol ten grains to an ounce. These metallic calces stimulate the absorbents into stronger action, whence the sluid has its saline part reabsorbed, and that before it has access to the air, which probably adds to its acrimony by oxygenating it and thus producing a new acid.

the roots of the hair, and is generally most virulent round the edges of the hair on the back part of the head; as the corona veneris appears most on the edges of the hair on the fore part of the head; for in these parts the eruption about the roots of the hair is most exposed to the external air, by which its acrimony

or noxious quality is increased.

The absorption of the matter thus oxygenated swells the lymphatics of the neck by its stimulus, occasioning many little hard lumps beneath the seat of the eruption; when this happens, the sooner it is cured the better, lest the larger lymphatics of the neck should become affected.

M. M. The art of curing these eruptions consists, first, in abating the inflammation, and consequent secretion of a noxious material. Secondly, in preventing its access to the air, which so much increases its acrimony. And thirdly, in promoting the absorption of it, before it has been exposed to the air. For these purposes venesection once, and gentle cathartics, which promote absorption by emptying the blood-vessels. Next poultices and fomentations, with warm water, abate inflammation by diluting the saline acrimony of the secreted sluid, and abating the painful sensation. Afterwards cerate joined with some metallic calx, as of zinc or lead, or solution of lead, mercury, or copper, or iron, which may stimulate the absorbent system into stronger action.

Cover the shaved head with tar and suet, and a bladder; this, by keeping the air from the secreted sluid, much contributes to its mildness, and the stimulus of the tar increases its absorption.

See the three preceding species of this genus.

Mr. Morison of Dublin cures the timea capitis'by what he terms an adhesive paste, which is made by boiling half a pound of sine flour in two pounds of common ale, and then adding four ounces of yellow resin in sine powder, and stirring them well together, until they are perfectly incorporated. After removing the hair, and poulticing the head for a day or two, to take off the hard scabs, this patte is spread on slips of linen, which are applied over the whole affected part, and removed and fresh ones applied every morning,—after one or two days, I suspect, that removing the plasters seldomer might be more advantageous.

12. Crusta lacten. Milk-crust is a milder disease than tinea, affecting the face as well as the hairy scalp of very young children. It is not infectious, nor liable to swell the lymphatics in its vicinity like the tinea.

M. M. Cover the eruption with cerate made with lapis calaminaris, to be renewed every day. Mix one grain of emetic tartar with forty grains of chalk, and divide into eight papers, one to be taken twice a day, or with magnefia alba, if it ools are wanted. The child should be kept cool and much in the air.

13. Trichoma. Plica polonica. A contagious disease, in which the hair is said to become alive and bleed, forming inextricable knots or plaits of great length, like the sabled head of Medusa, with intolerable pain, so as to confine the sufferer on his bed for years.

noxious

ORDO I.

Increased Sensation.

GENUS VI.

With Fever consequent to the Production of new Vessels or Fluids.

SPECIES.

1. Febris sensitiva. Sensitive fever, when unmixed with either irritative or inirritative fever, may be diftinguished from either of them by the less comparative diminution of muscular strength; or in other words, from its being attended with less diminution of the fenforial power of irritation. An example of unmixed fensitive fever may generally be taken from the pulmonary confumption; in this difease patients are seen to walk about with ease, and to do all the common offices of life for weeks, and even months, with a pulse of 120 strokes in a minute; while in other fevers, whether irritated or inirritated, with a pulse of this frequency, the patient generally lies upon the bed and exerts no muscular efforts without difficulty.

The cause of this curious phenomenon is thus to be underflood; in the fensitive fever a new sensorial power, viz. that of fensation, is superadded to that of irritation; which in other fevers alone carries on the increased circulation. Whence the power of irritation is not much more exhausted than in health; and those muscular motions, which are produced in consequence of it, as those which are exerted in keeping the body upright in walking, riding, and in the performance of many customary actions, are little impaired. For an account of the irritated fenfitive fever, see Class II. 1. 2. 1.; for the inirritated sensitive fever,

Class II. 1. 3. 1. IV. 2. 4. 11.

2. Febris a pure claufo. Fever from enclosed matter is generally of the irritated fensitive kind, and continues for many weeks, and even months, after the abfeefs is formed; but is diffinguished from the fever from aerated matter in open ulcers, because there are feldom any night-fweats, or colliquative diarrhoea in this, as in the latter. The pulse is also harder, and requires occasional venesection, and cathartics, to abate the inflammatory fever; which is liable to increase again every three or four days, till at length, unless the matter has an exit, it destroys the patient. In this fever the matter, not having been exposed to the air, has not acquired oxygenation; in which a new acid, or some other VOL. II.

noxious property, is produced; which acts like contagion on the constitution inducing fever-fits, called hertic fever, which terminate with sweats or diarrhea; whereas the matter in the closed abscess is either not absorbed, or does not so affect the circulation as to produce diurnal or hertic fever-fits; but the stimulus of the abscess excites so much sensation as to induce perpetual pyrexia, or inflammatory sever, without such marked remissions. Nevertheless there sometimes is no sever produced, when the matter is lodged in a part of little sensibility, as in the liver; yet a white pus-like sediment in those cases exists I believe generally in the urine, with occasional wandering pains about the region of the liver or chest.

3. Vomica. An abfects in the lungs is fometimes produced after peripheumony, the cough and shortness of breath continue in less degree, with distinctly in lying on the well side, and with fensitive irritated fever, as explained in the preceding article.

The occasional increase of fever, with hard pulse and fizy blood, in these patients, is probably owing to the inflammation of the walls of the vomica; as it is attended with difficulty of breathing, and requires venesection. Mr. B——; a child about seven years old, lived about seven weeks in this situation, with a pulse from 150 to 170 in a minute, without sweats, or diarrhæa, or sediment in his water, except mucus occasionally; and took sufficient nourishment during the whole time. The blood taken was always covered with a strong cupped fize, and on his death three or four pints of matter were found in one side of the chest; which had probably, but lately, been essued from a vomica. This child was frequently induced to swing, both in a reciprocating and in a rotatory swing, without any apparent absorption of matter; in both these swings he expressed pleasure, and did not appear to be vertiginous.

M. M. Repeated emetics. Digitalis? Perseverance in ro-

tatory swinging. See Class II. 1. 6. 7.

Mr. I. had laboured fome months under a vomica after a peripneumony, he was at length taken with a catarrh, which was in fome degree endemic in March 1795, which occasioned him to sneeze much, during which a copious hemorrhage from the lungs occurred, and he spit up at the same time half a pint of very fetid matter, and recovered. Hence errhines may be occasionally used with advantage.

4. Empyema. When the matter from an abscess in the lungs finds its way into the cavity of the chest, it is called an empyema. A servant man, after a violent peripneumony, was seized with symptoms of empyema, and it was determined, after some time, to perform the operation; this was explained to him, and

the usual means were employed by his friends to encourage him, by advising him not to be afraid." By which good advice he conceived so much fear, that he ran away early next morning, and returned in about a week quite well. Did the great fear promote the absorption of the matter, like the sickness occasioned by digitalis? Fear renders the external skin pale; by this continued decrease of the action of the absorbents of the skin might not those of the lungs be excited into greater activity? and thus produce increased pulmonary absorption by reverse sympathy, as it produces pale urine, and even stools, by direct sympathy?

M. M. Digitalis?

5. Febris Mesenterica. Fever from matter formed in the mesentery is probably more frequent than is suspected. It commences with pain in the bowels, with irritated sensitive sever; and continues many weeks, and even months, requiring occasional venesection, and mild cathartics; till at length the continuance of the pyrexia, or inflammatory sever, destroys the patient. This is an affection of the lymphatic glands, and properly belongs to scrosula; but as the matter is not exposed to the air, no hectic

fever, properly fo called, is induced.

6. Febris a pure aerato. Fever from aerated matter. A great collection of matter often continues a long time, and is sometimes totally absorbed, even from venereal buboes, without producing any disorder in the arterial system. At length, if it becomes putrid by its delay, and one part of the matter thus becomes aerated by the air given out by the other part; or if the ulcer has been opened, so that any part of it has been exposed to the air for but one day, a hectic sever is produced. Whence the utility arises of opening large abscesses by setons, as in that case little or no hectic sever is induced; because the matter is squeezed out by the side of the spongy threads of cotton, and little or no air is admitted; or by tapping the abscess with a trocar, as mentioned in ischias, Class II. 1. 2. 18.

In this fever the pulse is about 120 in a minute, and its access is generally in an evening, and sometimes about noon also, with sweats or purging towards morning, or urine with puslike sediment; and the patients bear this sever better than any other with so quick a pulse: and lastly, when all the matter from a concealed ulcer is absorbed, or when an open ulcer is healed, the hectic sever ceases. Here the absorbed matter is supposed to produce the sever, and the diarrhæa, sweats, or copious muddy urine, to be simply the consequence of increased secretion, and not to consist of the purulent matter, which was supposed to be absorbed from the ulcer. See Sudor calidus, Class I. 1. 2. 3.

The action of the air on ulcers, as we have already shewn, in-

creases the acrimony of the purulent matter, and even converts it into a weaker kind of contagious matter; that is, to a material inducing fever. This was ascribed to the union of the azotic part of the atmosphere with the effused pus in Sect. XXVIII. 2. but by contemplating more numerous facts and analogies, I am now induced to believe, that it is by the union of oxygen with it; first, because oxygen so greedily unites with other animal substances, as the blood, that it will pass through a most bladder to combine with it, according to the experiment of Dr. Priestley. Secondly, because the possons of venomous creatures are supposed to be acids of different kinds, and are probably formed by the contact of air after their secretion. And lastly, because the contagious matter from other ulcers, as in itch, or small-pox, is formed on external membranes, and are probably combinations of animal matter and oxygen, producing other new acids.

Since having written the above, Dr. Mitchill, of New York, has spoken much of the septic quality of azote, or nitrogen; and thinks that it is the union of this part of the atmosphere with the matter of ulcers, which produces or increases its contagious or sever-exciting property; which I had myself at first believed, as mentioned in Part I. Sect XXVIII. 2. In support of this opinion, it may be said, that proper ventilation with purer air is believed certainly to diminish or destroy infection; as spoken of in Class II. 1. 3. where it is proposed to disengage oxygen from manganese, for the purpose of purifying crowded apartments. But surther experiments must determine this curious inquiry; which might be attended with important consequences, if azote, and not oxygen, could be shewn to prevent the healing of pulmonary ulcers; as oxygen might be respired alone, or mixed with hydrogen or with carbonic acid gas, instead of with azote.

It was thought a subject of consequence by the Æsculapian Society at Edinburgh, to find a criterion which should distinguish pus from mucus, for the purpose of more certainly discovering the presence of ulcers in pulmonary diseases, or in the urinary passages. For this purpose that society offered their first gold medal, which was conferred on the late Mr. Charles Darwin, in the year 1778, for his experiments on this subject. From which he deduces the following conclusions:

" 1. Pus and mucus are both foluble in the vitriolic acid, though in very different proportions, pus being much the lefs foluble.

"2. The addition of water to either of these compounds decomposes it; the mucus thus separated, either swims on the mixture, or forms large slocci in it; whereas the pus falls to the bottom, and forms on agitation a uniform turbid mixture.

"3. Pus

- "3. Pus is diffusible through a diluted vitriolic acid, though mucus is not; the same occurs with water, or a solution of scale
- "4. Nitrous acid dissolves both pus and mucus; water added to the folution of pus produces a precipitate; and the fluid above becomes clear and green; while water and the solution of mucus form a dirty coloured fluid.

" 5. Alkaline lixivium diffolves (though fometimes with diffi-

culty) mucus, and generally pus.

" 6. Water precipitates pus from such a solution, but does not

mucus.

- "7. Where alkaline lixivium does not dissolve pus, it still distinguishes it from mucus; as it then prevents its dissussion through water.
- "8. Coagulable lymph is neither foluble in diluted nor concentrated vitriolic acid.
- " 9. Water produces no change on a folution of ferum in alkaline lixivium, until after long standing, and then only a very slight fediment appears.

" 10. Corrosive sublimate coagulates mucus, but not pus.

"From the above experiments it appears, that strong vitriolic acid and water, diluted vitriolic acid, and caustic alkaline lixivium and water, will serve to distinguish pus from mucus; that the vitriolic acid can separate it from coagulable lymph, and

alkaline lixivium from ferum.

"And hence, when a person has any expectorated material, the composition of which he wishes to ascertain, let him dissolve it in vitriolic acid, and in caustic alkaline lixivium; and then add pure water to both solutions: and if there is a fair precipitation in each, he may be affured that some pus is present. If in neither a precipitation occurs, it is a certain test, that the material is entirely mucus. If the material cannot be made to dissolve in alkaline lixivium by time and trituration, we have also reason to believe that it is pus." Experiments on Pus and Mucus. Cadell. London.

Dr. Cappe, of York, in his inaugural treatise de Hectica, and Dr. Ryan, of Dublin, in his Essay on Consumption, have repeated these experiments of Mr. Darwin with nearly similar results.

7. Phthis pulmonalis. In pulmonary confumption the fever is generally supposed to be the consequence of the stimulus of absorbed matter circulating in the blood-vessels, and not simply of its stimulus on their extremities in the surface of the ulcers; as mentioned in Class II. 1. 5. and Class II. 1. 3. 9. The ulcers are probably sometimes occasioned by the putrid acrimony of effused blood remaining in the air-cells of the lungs after an hamoptoe.

hæmoptoe. See Class I. 2. 1. 9. The remote cause of confumption is ingeniously ascribed by Dr. Beddoes to the hyperoxygenation of the blood, as mentioned Section XXVIII. 2.

As the patients liable to confumption are of the inirritable temperament, as appears by the large pupils of their eyes; there is reason to believe, that the hamoptoe is immediately occasioned by the deficient absorption of the blood at the extremities of the bronchial vein; and that one difficulty of healing the ulcers is occasioned by the deficient absorption of the fluids effused into them. See Sect. XXX. 1, and 2.

The difficulty of healing pulmonary ulcers may be owing, as its remote cause, to the incessant motion of all the parts of the lungs; whence no scab, or indurated mucus, can be formed so as to adhere on them. Whence these naked ulcers are perpetually exposed to the action of the air on their surfaces, converting their mild purulent matter into a contagious ichor; which not only prevents them from healing, but by its action on their circumferences, like the matter of itch or timea, contributes to spread them wider. See the preceding article, and Sect. XXXIII.

This acidifying principle is found in all the metallic calces. as in lapis calaminaris, which is a calciform ore of zinc; and in minium, which is a calx of lead; two materials which are powerful in healing excoriations and ulcers, in a short time, by their external application. How then does it happen, that the oxygen in the atmosphere should prevent pulmonary ulcers from healing, and even induce them to fpread wider; and yet in its combination with metals, it should facilitate their healing? The healing of ulcers confifts in promoting the absorption of the sluids effused into them, as treated of in Section XXXIII. 3. 2. Oxygen in combination with metals, when applied in certain quantity, produces this effect by its stimulus; and the metallic oxydes not being decomposed by their contact with animal matter, no new acid, or contagious material, is produced. So that the combined oxygen, when applied to an ulcer, fimply I suppose promotes absorption in it, like the application of other materials of the articles forbentia or incitantia, if applied externally; as opium, bark, alum. But in the pulmonary ulcers, which cannot protect themselves from the air by forming a fcab, the uncombined oxygen of the atmofphere unites with the purulent matter, converting it into a contagious ichor; which by infection, not by erofion, enlarges the ulcers, as in the itch or tinea; which might hence, according to Dr. Beddoes's ingenious theory of confumption, be induced to heal, if exposed to an atmosphere deprived of a part of its oxygen.

oxygen. This I hope future experiments will confirm, and that the pneumatic medicine will alleviate the evils of mankind

in many other, as well as in this most fatal malady.

M. M. First, the respiration of air lowered by an additional quantity of azote, or mixed with some proportion of hydrogen, or of carbonic acid air, may be tried; as described in a late publication of Dr. Beddoes on the medicinal use of factitious airs. Johnson, London. Or lattly, by breathing a mixture of one-tenth part of hydrocarbonate mixed with common air, according to the discovery of Mr. Watt, which has a double advantage in these cases, of diluting the oxygen of the atmospheric air, and inducing sickness, which increases pulmonary absorption, as mentioned below. An atmosphere diluted with fixed air (carbonic acid) might be readily procured by setting tubs of new wort, or fermenting beer, in the parlour and lodging-room of the patient. For it is not acids sloating in the air, but the oxygen or acidifying principle, which injures or enlarges pulmonary ulcers by combining with the purulent matter.

Another eafy method of adding carbonic acid gas to the air of a room, would be by means of an apparatus invented by Mr. Watt, and fold by Bolton and Watt, at Birmingham, as described in Dr. Beddoes' Treatise on Pneumatic Medicine. Johnson, London. It consists of an iron pot, with an arm projecting, and a method of letting water drop by slow degrees on chalk, which is to be put into the iron pot, and exposed to a moderate degree of heat over a common fire. By occasionally adding more and more chalk, carbonic acid gas might be carried through a tin pipe from the arm of the iron pot to any part of the room near the patient, or from an adjoining room. In the same manner a diffusion of solution of slowers of zinc might be produced and breathed by the patient, and would be likely much to contribute to the healing of pulmonary ulcers; as observed by Mr. Watt. See the treatise above mentioned.

Breathing over the vapour of caustic volatile alkali might easily be managed for many hours in a day; which might neutralize the acid poison formed on pulmonary ulcers by the contact of oxygen, and thus prevent its deleterious quality, as other acids become less caustic, when they are formed into neutral salts with alkalis. The volatile salt should be put into a tin canister, with two pipes like horns from the top of it, one to suck the air from,

and the other to admit it.

Secondly, the external ulcers in scrosulous habits are pale and flabby, and naturally difinclined to heal, the deposition of fluids in them being greater than the absorption; these ulcers have their appearance immediately changed by the external application

of metallic calxes, and the medicines of the article Sorbentia, fuch as ceruffa and the bark in fine powder, see Class I. 2. 3. 214 and are generally healed in a short time by these means. Induced by these observations, I wished to try the external application of fuch powders to ulcers in the lungs, and constructed a box with a circulating brush in it, into this box two ounces of fine powder of Peruvian bark were put, and two drachms of cerusia in fine powder; on whirling the central brush, part of this was raifed into a cloud of powder and the patient, applying his mouth to one of the tin pipes rising out of the box, inhaled this powder twice a day into his lungs. I observed it did not produce any cough or uneafiness. This patient was in the last stage of confumption, and was fron tired of the experiment, nor have I had fuch patients as I wished for the repetition of it. Perhaps a fine powder of manganese, or of the flowers of zinc, or of lapis calaminaris, might be thus applied to ulcers of the lungs with greater advantage? Perhaps air impregnated with flowers of zinc in their most comminuted state, might be a better way of applying this powder to the lungs, as discovered by Mr. Watt. See Dr. Beddoes on Pneumatic Medicine. Johnson.

Thirdly, as the healing of an ulcer confifts in producing a tendency to absorption on its surface greater than the deposition on it; see Sect. XXXIII. 3. 2. Other modes of increasing pulmonary absorption, which are perhaps more manageable than the preceding ones, may be had recourse to; such as by producing frequent nausea or sickness. See Sect. XXIX. 5. 1. and Art. IV. 2. The great and sudden absorption of sluid from the lungs in the anasarca pulmonum by the sickness induced by the exhibition of digitalis, assonishes those who have not before attended to it, by emptying the swelled limbs, and removing the

difficulty of breathing in a few hours.

The most manageable method of using digitalis is by making a saturated tincture of it, by insusing two ounces of the powder of the leaves in a mixture of four ounces of rectified spirit of wine, and four ounces of water. Of this from 30 to 60 drops, or upwards, from a two-ounce phial, are to be taken twice in the morning part of the day, and to be so managed as not to induce violent sickness. If sickness nevertheless comes on, the patient must for a day or two omit the medicine; and then begin it again in reduced doses.

Mr. —, a young man about twenty, with dark eyes and large pupils, who had every fymptom of pulmonary ulcers, I believed to have been cured by digitalis, and published the case in the Transactions of the College, Vol. III. But I heard, that about two years afterwards he relapsed and died. Mr.

L_____, a corpulent man, who had for fome weeks laboured under a cough with great expectoration, with quick pulse, and difficulty of breathing, foon recovered by the use of digitalic taken twice a day; and though this case might probably be a peripneumonia notha, or catarrh, it is here related as shewing the power of pulmonary absorption excited by the use of this

drug.

Since the publication of the above, some successful cases of the treatment of confumption by the tincture of digitalis are related in Medical and Physical Contributions, edited by Dr. Beddoes, Longman, London. Two of the fuccessful cases are from Dr. Drake, who observes, "that by gradually increasing the dose of the faturated tincture of digitalis from 20 drops to 100 twice a day, all the fymptoms of fever, cough, pain, and dyspnœa, daily grew better, and at length totally ceased, and that on the quantity and quality of the expectorated matter the digitalis foon exerted a very remarkable effect, either promoting its absorption, or diminishing its secretion, or perhaps both, in a rapid manner; while at the same time it deprived it of its fetor." Many cases with great relief, or with prosperous event, are related by Dr. Fowler, and by Dr. Beddoes. One I have also lately seen myfelf, whom I believed to be confumptive, and who is of a confumptive family, and after having used the saturated tincture about fix weeks, or two months, in various doses, is now believed by herfelf and friends to be perfectly restored to health, but there has not been time enough yet elapsed to determine, whether she may not relapse, now she discontinues the medicine.

Nevertheless as the digitalis has been given in many cases without success, there is reason to believe, that it should be taken early in the disease, before too great ulcerations are produced, and too great debility exists. As these patients are subject to slatter themselves more than most others, and are liable, on that account, not to apply soon enough for proper assistance, they should be warned that a cough attended with a pulse, that beats

120 times in a minute, is always a difease of danger.

Another method of inducing fickness, and pulmonary absorption in consequence, is by sailing on the sea; by which many consumptive patients have been said to have received their cure; which has been erroneously ascribed to sea-air, instead of sea-sickness; whence many have been sent to breathe the sea-air on the coasts, who might have done better in higher situations, where the air probably contains less oxygen gas, which is the heaviest part of it. See a Letter from Dr. J. C. below.

A third method of inducing fickness, and consequent pulmonary absorption, is by the vertigo occasioned by swinging; which

has lately been introduced into practice by Dr. Smith, (Effay on Pulmonary Confumption), who observed that by swinging the hectic pulse became flower, which is explained in Class IV. 2.

1. 10. The usual way of reciprocating swinging, like the oscillations of a pendulum, produces a degree of vertigo in those, who are unused to it; but to give it greater effect, the patient should be placed in a chair suspended from the ceiling by two parallel cords in contact with each other, the chair should then be forcibly revolved 20 or 40 times one way, and suffered to return spontaneously; which induces a degree of sickness in most adult people, and is well worthy an exact and pertinacious trial, for an hour or two, three or four times a day for a month.

The common means of promoting abforption in ulcers, and of thickening the matter in confequence, by taking the bark and opium internally, or by metallic falts, as of mercury, steel, zinc, and copper, in small quantities, have been repeatedly used in pulmonary confumption; and may have relieved some of the symptoms. As mercury cures venereal ulcers, and as pulmonary ulcers refemble them in their not having a disposition to heal, and in their tendency to enlarge themselves, there were hopes, from analogy, that it might have fucceeded. Would a folution of gold in aqua regia be worth trying? When vinegar is applied to the lips, it renders them instantly pale, by promoting the venous absorption; if the whole skin was moistened with warmish vinegar, would this promote venous absorption in the lungs by their sympathy with the skin? The very abstemious diet on milk and vegetables alone is frequently injurious. Flesh meat once a day, with fmall wine and water, or fmall beer, is pref-Half a grain of opium twice a day, or a grain, I believe to be of great use at the commencement of the disease, as appears from the subsequent case.

Miss —, a delicate young lady, of a confumptive family, when she was about eighteen, had frequent cough, with quick pulse, a pain of her side, and the general appearances of a beginning confumption. She took about five drops of laudanum twice a day in a faline draught, which was increased gradually to ten. In a few weeks she recovered, was afterwards married, bore three or four children, and then became consumptive and

died.

The following case of hereditary comfumption is related by a physician of great ability and very extensive practice; and, as it is his own case, abounds with much nice observation and useful knowledge; and, as it has been attended with a favourable event, may give consolation to many, who are in a similar situation; and shews that Sydenham's recommendation of riding as

a cure for consumption is not so totally inessectual, as is now

commonly believed.

I. C. aged 27, with black hair, and a ruddy complexion, was fubiect to cough from the age of puberty, and occasionally to fpitting of blood. His maternal grandfather died of confumption under thirty years of age, and his mother fell a victim to this difease, with which she had long been threatened, in her 43d year, and immediately after she ceased to have children. In the fevere winter of 1783-4, he was much afflicted with cough; and being exposed to intense cold, in the month of February he was feized with peripneumony. The difease was violent and dangerous, and after repeated bleedings as well as blifterings, which he supported with disficulty, in about fix weeks he was able to leave his bed. At this time the cough was fevere, and the expectoration difficult. A fixed pain remained on the left side, where an issue was inserted; regular hectic came on every day about an hour after noon, and every night heat and restlessness took place, succeeded towards morning by general perspiration.

The patient, having formerly been subject to ague, was struck with the resemblance of the sebrile paroxysm, with what he had experienced under that disease, and was willing to flatter himself it might be of the same nature. He therefore took bark in the interval of sever, but with an increase of his cough, and this requiring venesection, the blood was found highly inflammatory. The vast quantity of blood which he had lost from time to time, produced a disposition to fainting, when he resumed the upright posture, and he was therefore obliged to remain almost constantly in a recumbent position. Attempting to ride out in a carriage, he was surprised to find that he could sit upright for a considerable time, while in motion, without inconvenience, though, on stopping the carriage, the disposition to fainting returned.

At this time, having prolonged his ride beyond the usual length, he one day got into an uneven road at the usual period of the recurrence of the hectic paroxysms, and that day he missed it altogether. This circumstance led him to ride out daily in a carriage at the time the febrile accession might be expected, and sometimes by this means it was prevented, sometimes de-

ferred, and almost always mitigated.

This experience determined him to undertake a journey of fome length, and Bristol being, as is usual in such cases, recommended, he set out on the 10th of April, and arrived there on the 2d of May. During the greater part of this journey (of 175 miles) his cough was severe, and being obliged to be bled three different times on the road, he was no longer able to set up-

right,

right, but at very short intervals, and was obliged to lie at length in the diagonal of a coach. The hectic paroxysms were not interrupted during the journey, but they were irregular and indistinct, and the falutary effects of exercise, or rather of gestation,

were impressed on the patient's mind.

At Briftol he stayed a month, but reaped no benefit. The weather was dry and the roads dusty; the water insipid and inert. He attempted to ride on horseback on the downs, but was not able to bear the satigue for a distance of more than a hundred yards. The necessity of frequent bleedings kept down his strength, and his hectic paroxysms continued, though less severe. At this time, suspecting that his cough was irritated by the west winds bearing the vapour from the sea, he resolved to try the effects of an inland situation, and set off for Matlock in Derbyshire.

During the journey he did not find the improvement he expected, but the nightly perspirations began to diminish; and the extraordinary fatigue he experienced proceeded evidently from his travelling in a post-chaife, where he could not indulge in a recumbent position. The weather at Bristol had been hot, and the earth arid and dusty. At Matlock, during the month of June 1784, there was almost a perpetual drizzle, the soil was wet, and the air moist and cold. Here, however, the patient's cough began to abate, and at intervals he found an opportunity of riding more or less on horseback. From two to three hundred yards at a time, he got to ride a mile without stopping; and at length he was able to fit on horseback during a ride from Mason's Bath to the village of Matlock along the Derwent, and round on the opposite banks, by the works of Mr. Arkwright, back to the house whence he started, a distance of five miles. On dismounting, however, he was feized with diliquium, and foon after the strength he had recovered was lost by an attack of the hæmorrhoids of the most painful kind, and requiring much loss of blood from the parts affected.

On reflection, it appeared that the only benefit received by the patient was during motion, and continued motion could better be obtained in the course of a journey than during his residence at any particular place. This, and other circumstances of a private but painful nature, determined him to set out from Matlock on a journey to Scotland. The weather was now much improved, and during the journey he recruited his strength. Though as yet he could not sit upright at rest for half an hour together without a disposition to giddiness, dimness of sight, and diliquium, he was able to sit upright under the motion of a post-chaise during a journey of from 40 to 70 miles daily, and his

appetite began to improve. Still his cough continued, and his hectic flushings, though the chills were much abated and very

irregular.

The falutary effects of motion being now more striking than ever, he purchased a horse admirably adapted to a valetudinarian in Dumfriesshire, and being now able to sit on horseback for an hour together, he rode out several times a day. He fixed his residence for a few weeks at Mosfat, a village at the foot of the mountains whence the Tweed, the Clyde, and the Annan, descend in different directions; a situation inland, dry, and healthy, and elevated about three hundred feet above the surface of the sea. Here his strength recovered daily, and he began to eat animal food, which for several months before he had not tasted. Persevering in exercise on horseback, he gradually increased the length of his rides, according to his strength, from sour to twenty miles a day; and returning on horseback to Lancashire by the lakes of Cumberland, he arrived at Liverpool on the first of September, having rode the last day of his journey forty miles.

The two inferences of most importance to be drawn from this narrative, are, first, the extraordinary benefit derived from gestation in a carriage, and still more the mixture of gestation and exercise on horseback, in arresting or mitigating the hestic paroxysm; and secondly, that in the florid consumption, as Dr. Beddoes terms it, an elevated and inland air is in certain circumstances peculiarly salutary; while an atmosphere loaded with the spray of the sea is irritating and noxious. The vicinity of the sea appears very injurious to almost all vegetables, and should on that account be suspected in respect to its general salubrity, though it may nevertheless be medicinal in some diseases, if resorted to for a time in the summer months, but must be ineligible as a permanent residence. See Class I. 2. 1. 15.

The benefit derived in this case from exercise on horseback, may lead us to doubt whether Sydenham's praise of this remedy be as much exaggerated as it has of late been supposed. Since the publication of Dr. C. Smyth on the effects of swinging in lowering the pulse in the hectic paroxysm, the subject of this narrative has repeated his experiments in a great variety of cases, and has confirmed them. He has also repeatedly seen the hectic paroxysm prevented, or cut short, by external ablution of the

naked body with tepid water.

So much was his power of digestion impaired or vitiated by the immense evaucations, and the long continued debility he underwent, that after the cough was removed, and indeed for several years after the period mentioned, he never could eat animal food without heat and slushing, with frequent pulse and extreme

drowfinefs.

drowfinefs. If this drowfinefs was encouraged, the fever ran high, and he awoke from diffurbed fleep, wearied and depreffed. If it was refolutely refifted by gentle exercife, it went off ir about an hour, as well as the increased frequency of the pulse. This agitation was however such as to incapacitate him during the afternoon for study of any kind. The same effects did not follow a meal of milk and vegetables, but under this diet his strength did not recruit; whereas after the use of animal food it recovered rapidly, notwithstanding the inconvenience already mentioned. For this inconvenience he at last found a remedy in the use of cosse immediately after dinner, recommended to him by his friend Dr. Percival. At first this remedy operated like a charm, but by frequent use, and indeed by abuse, it no longer possesses its original efficacy.

Dr. Falconer, in his Differtation on the Influence of the Paffions and Affections of the Mind on Health and Difease, supposes that the cheerfulness which attends hectic fever, the ever-fpringing hope, which brightens the gloom of the consumptive patient, increases the diseased actions, and hastens his doom. And hence he is led to inquire, whether the influence of fear might not be substituted in such cases to that of hope with advantage to the patient? This question I shall not presume to answer, but it leads me to say something of the state of the mind.

in the case just related.

The patient, being a physician, was not ignorant of his danger, which fome melancholy circumstances served to impress on his mind. It has already been mentioned, that his mother and grandfather died of this discase. It may be added, that in the year preceding that on which he himself was attacked, a fifter of his was carried off by confumption in her 17th year; that in the same winter in which he fell ill, two other fifters were feized with the fame fatal disorder, to which one of them fell a victim during his residence at Bristol, and that the hope of bidding a last adieu to the other was the immediate cause of his journey to Scotland, a hope which, alas! was indulged in vain. The day on which he reached the end of his journey, her remains were committed to the dust! It may be conjectured from these circumstances, that whatever benefit may be derived from the apprehension of death, must in this case have been obtained. The expectation of this iffue was indeed for some time to fixed that it ceased to produce much agitation; in conformity to that general law of our nature, by which almost all men submit with composure to a fate that is foreseen, and that appears inevitable. As however the progress of disease and debility feemed to be arrested, the hope and the love of life revived, and produced, from time to time, the observations and the

exertions already mentioned.

Wine and beer were rigorously abstained from during fix months of the above history; and all the blood, which was ta-

ken, was even to the last buffy. Feb. 3, 1795.

It has lately been afferted, that the people of Holland are less liable to confumption of the lungs, than those of many other parts of Europe, which has been afcribed to their warmer clothing. I am aware of the difficulty of making fuch estimates with any great degree of certainty, but if fuch be the fact, it may indeed be ascribed with some degree of probability to their using very warm clothing, but not very warm rooms during the winter feafon. Whence the lungs are not fo much exposed to the great and sudden transition from very warm rooms into frosty air, as in this country. And though the lungs have not a fenfation of cold or of chilne's like the external skin, in passing from very warm air into great cold, often much below the freezing point, yet they are liable to inflammation, like other parts of the fystem. But to this may be objected, that the hereditary pulmonary confumption attacks the patient fo infallibly a few years after puberty, that it does not appear to depend much on external circumstances.

8. Febris scrosulosa. The hectic fever occasioned by ulcers of the lymphatic glands, when exposed to the air, does not differ from that attending pulmonary confumption, being accompanied with night-sweats and occasional diarrheea.

M. M. The bark. Opium internally. Externally ceruffa and bark in fine powder. Bandage. Sea-bathing. See Class

I. 2. 3. 21. and II. 1. 4. 12.

9. Febris ischiadica. A hectic fever from an open ulcer between the muscles of the pelvis, which differs not from the preceding. If the matter in this situation lodges till part of it, I suppose, becomes putrid, and aerates the other part; or till it becomes absorbed from some other circumstance; a similar hectic

fever is produced, with night-fweats, or diarrhoea.

Mrs. —, after a lying in, had pain on one fide of her loins, which extended to the internal part of the thigh on the fame fide. No fluctuation of matter could be felt; the became hectic with copious night-fweats, and occasional diarrhoea, for four or five weeks; and recovered by, I suppose, the total absorption of the matter, and the reunion of the walls of the abscess. See Class II. 1. 2. 18.

10. Febris Arthropuodica. Fever from the matter of diseased joints. Does the matter from suppurating bones, which gener-

ally has a very putrid fmell, produce hectic fever or typhus? See Class II. 1. 4. 16.

When the contagious matters have been produced on the external habit, and in process of time become absorbed, a fever is produced in consequence of this reabsorption; which differs with the previous irritability or inirritability, as well as with the

fenfibility of the patient.

12. Febris variolosa secundaria. Secondary fever of small-pox. In the distinct small-pox the fever is of the sensitive irritated or inflammatory kind; in the confluent small-pox it is of the sensitive inirritated kind, or typhus gravior. In both of them the fwelling of the face, when the matter there begins to be abforbed, and of the hands, when the matter there begins to be abforbed, shew, that it stimulates the capillary vessels or glands, occasioning an increased secretion greater than the absorbents can take up, like the action of the cantharides in a blifter; now as the application of a blifter on the skin frequently occasions the strangury, which shews, that some part of the cantharides is absorbed; there is reason to conclude, that a part of the matter of small-pox is absorbed, and thus produces the secondary fever. See Class II. 1. 3. 9. And not simply by its stimulus on the furface of the ulcers beneath the scabs. The exfudation of a vellow fluid from beneath the confluent eruptions on the face before the height is spoken of in Class II. 1. 3. 2.

The material thus absorbed in the secondary fever of small-pox differs from that of open ulcers, as it is only aerated through the elevated cuticle; and secondly, because there is not a constant supply of fresh matter, when that already in the pustules is exhausted, either by absorption, or by evaporation, or by its induration into a scab. Might not the covering the sace assiduously and exactly with plasters, as with cerate of calamy, or with minium plaster, by precluding the air from the pustules, prevent their contracting a contagious, or acescent, or sever-producing power? and the secondary sever be thus prevented entirely. If the matter in those pustules on the face in the consluent small-pox were thus prevented from oxygenation, it is highly probable, both from this theory, and from the facts before mentioned, that the matter would not erode the skin beneath them, and by

these means no marks or scars would succeed.

13. Febris carcinomatofa. Fever from the matter of cancer. In a late publication the pain is faid to be relieved, and the fever cured, and the cancer eradicated, by the application of carbonic acid gas, or fixed air. See Class II. 1. 4. 16.

14. Febris

14. Febris venerea. From the absorption of the matter from venereal ulcers and suppurating bones. See Syphilis, II. 1. 5. 2. M. M. Any mercurial calx. Sarsaparilla? Mezereon?

parts of the body are destroyed by external violence, as a bruise, or by mortification, a putrefaction soon succeeds; as they are kept in that degree of warmth and moisture, by their adhesion to the living parts of the body, which most forwards that procees. Thus the sloughs of mortified parts of the tonsils give fetor to the breath in some severs; the matter from putrefying teeth, or other suppurating bones, is particularly offensive; and even the scurf, which adheres to the tongue, frequently acquires a bitter taste from its incipient putridity. This material differs from those before mentioned, as its deleterious property depends

on a chemical rather than an animal process.

16. Febris puerpera. Puerperal fever. It appears from some late diffections, which have been published, of those women who have died of the puerperal fever, that matter has been formed in the omentum, and found in the cavity of the abdomen, with fome blood or fanies. These parts are supposed to have been injured by the exertions accompanying labour; and as matter in this viscus may have been produced without much pain, this difease is not attended with arterial strength and hard full pulse. like the inflammation of the uterus; and as the fever is of the inirritative or typhus kind, there is reason to believe, that the previous exhaustion of the patient during labour may contribute to its production; as well as the absorption of a material not purulent but putrid; which is formed by the delay of extravafated or dead matter produced by the bruiles of the omentum. or other viscera, in the efforts of parturition, rather than by purulent matter, the consequence of suppuration. The pulse is generally about 120 when in bed, and in the morning; and is increased to 134, or more, when the patient sits up, or in the evening paroxyim. The pulse of all very weak patients increases in frequency when they fit up; because the expenditure of fenforial power necessary to preserve an erect posture deducts so much from their general strength; and hence the pulse becomes weaker and in consequence quicker. See Sect. XII. 1. 4.

Whence I suspect that the puerperal sever is distinguished from the hestic sever, by the former being produced and supported by the absorption of a putrid sanies, arising from dead parts of the omentum or mesentery; and the latter being produced and supported by the absorption of purulent matter, which is the consequence of inflammation, after it has been oxygenated by exposure to the air; and that hence they differ in

Vol. II. KK

the greater debility, and confequent quicker pulse, and more rapid progress of the former than the latter; but agree, in the few patients which I have attended, in the circumstance of the patients bearing the quantity of these fevers better than the typhus, as is feen in their frequent rifing from their beds for hours, and even attending to their occupations with a pulse of more than 120 in a minute; and also in another important circumstance, which is, that they take folid food, as bread, and eggs, and oysters, and even chicken, in great quantities; which in the inirritative fever, or typhus, is refused during the whole course of the disease. And hence it seems probable, that the cause or commencement of the inirritative fever, or typhus, may have been from the torpor or paralysis of the stomach, owing to the fwallowing of contagious matter along with our faliva; and the actions of the heart fuffer in confequence from fympathy. And that hence these three kinds of fever may be distinguished from each other: the typhus, by the total loss of appetite for folid food; the hectic fever, by the pulse being feldom above 120, and with attendant inflammation; and the puerperal fever, by a quicker and weaker pulse; but both the latter existing without the inability to take fome folid nourishment.

In this fever time must be allowed for the absorption of the matter. Very large and repeated quantities of the bark, by preventing sufficient food from being taken, as bread, and wine, and water, I have thought, have much injured the patient; for the bark is not here given, as in intermittent fevers, to prevent the paroxysm, but simply to strengthen the patient by increasing the power of digestion. About two ounces of decoction of bark, with four drops of laudanum, and a drachm of sweet spirit of vitriol, once in six hours, and a glass of wine between those times, with panada, or other food, I have thought of most ad-

vantage, with a fmall blifter occasionally.

Where not only the stomach but also the bowels are much distended with air, so as to sound on striking them with the singers, the case is always dangerous, generally hopeless; which is more so in proportion to the quickness of the pulse. Where the bowels are distended two drops of oil of cinnamon should be given in the panada three or sour times a day, with ten grains of alum.

In one case of puerperal sever, which lasted above forty days, and was attended for the last fortnight with perpetual subsultus of the tendons, and even twitching of the hands with unceasing delirium, and inability to sleep, musk given in the dose of ten grains every six hours, with sive drops of tincture of opium, seemed to be of service; and when the abdomen became tumid

with air, about the 36th day from the commencement of the fever, alum given in doses of about seven grains every three hours, feemed of uncommon fervice, as the tumour of the abdomen much fubfided in one day, and the patient immediately became able to fleep two or three hours at a time; but the event of the disease was fatal.

In this fituation I suppose the fever to have been kept up by the absorption of a putrid material in the abdomen, on the outfide of the intestines; and as alum instantaneously destroys the volatile alkali which occasions a part of the smell, and perhaps the whole of the gas of putrid matter; which alkali precipitates the argillaceous earth from the vitriolic acid; I suppose this effect would be produced by alum, though it might not be produced by vitriolic acid, as the latter would unite with the contents of the stomach; but the alum would not unite with any thing, till it became exposed to exhalations of putrid matter. See Class II. 1. 3. 1. Might not a puncture by a lancet into the tumid abdomen, through the scar of the navel, be of use, when it is much distended with air?

The want of fleep was owing to debility, and ceafed when that became lessened. As some motions of the hands were the consequence of her delirious ideas, these became tremulous, like the hands of very old men, or drunkards, from debility whenev-

er they were exerted.

A very interesting account of the puerperal fever, which was epidemic at Aberdeen, has been lately published by Dr. Alexander Gordon. (Robinsons, London.) In several diffections of those who died of this disease, purulent matter was found in the cavity of the abdomen; which he ascribes to an erysipelatous inflammation of the peritonæum, as its principal feat, and of its productions, as the omentum, mesentery, and peritonæal coat of the intestines.

He believes, that it was infectious, and that the contagion was always carried by the accoucheur, or the nurse, from one ly-

ing-in woman to another.

The disease began with violent unremitting pain of the abdomen on the day of delivery, or the next day, with shuddering, and very quick pulse, often 140 in a minute. In this fituation, if he faw the patient within 12 or 24 hours of her feizure, he took away from 16 to 24 ounces of blood, which was always fizy. He then immediately gave a cathartic, confifting of three grains of calomel, and forty grains of powder of jalap. After this had operated, he gave an opiate at night; and continued the purging and the opiate for feveral days.

He afferts, that almost all those, whom he was permitted to

treat in this manner early in the disease, recovered, to the number of 50; and that almost all the rest died. But that when two or three days were elapsed, the patient became too weak for this method; and the matter was already formed, which destroyed them. Except that he saw two patients who recovered, after discharging a large quantity of matter at the navel. And a few who were relieved, by the appearance of external eryfipelas on the extremities.

This difease, confisting of an erysipelatous inflammation, may occasion the great debility sooner to occur than in inflammation of the uterus; which latter is neither erysipelatous, I suppose, nor contagious. And the fuccess of Dr. Gordon's practice feems to correspond with that of Dr. Rush, in the contagious fever or plague at Philadelphia; which appeared to be much affifted by early evacuations. One case I saw, some time ago. where violent unceasing pain of the whole abdomen occurred, a few hours after delivery, with quick pulse; which ceased after the patient had twice lost about eight ounces of blood, and had taken a moderate cathartic with calomel.

This case induces me to think, that it might be safer, and equally efficacious, to take less blood at first than Dr. Gordon mentions, and to repeat the operation in a few hours, if the continuance of the symptoms should require it. And the same in respect to the cathartic, which might perhaps be given in less

quantity, and repeated every two or three hours.

Nor should I wish to give an opiate after the first venesection and cathartic; as I suspect that this might be injurious, except those evacuations had emptied the vessels so much, that the stimulus of the opiate should act only by increasing the absorption of the new vessels or fluids produced on the surfaces of the inflamed membranes. In other inflammations of the bowels, and in acute rheumatism, I have seen the disease much prolonged, and I believe fometimes rendered fatal, by the too early adminiftration of opiates, either along with cathartics, or at their intervals; while a fmall dose of opium given after sufficient evacuations produces abforption only by its stimulus, and much contributes to the cure of the patient. We may have visible testimony of this effect of opium, when a folution of it is put into an inflamed eye; if it be thus used previous to sufficient evacuation, it increases the inflammation; if it be used after sufficient evacuation, it increases absorption only, and clears the eye in a

I cannot omit observing, from considering these circumstances, how unwife is the common practice of giving an opiate to every woman

woman immediately after her delivery, which must often have been of dangerous confequence.

17. Febris a sphacelo. Fever from mortification. This fever from absorption of putrid matter is of the inirritative or typhus

kind. See the preceding article.

M. M. Opium and the bark are frequently given in too great quantity, so as to induce consequent debility, and to oppress the power of digestion.

ORDO I.

Increased Sensation.

GENUS VII.

With increased Action of the Organs of Sense.

SPECIES.

1. Delirium febrile. Paraphrofyne. The ideas in delirium consist of those excited by the sensation of pleasure or pain, which precedes them, and the trains of other ideas associated with these and not of those excited by external irritations or by voluntary exertion. Hence the patients do not know the room which they inhabit, or the people who surround them; nor have they any voluntary exertion, where the delirium is complete; so that their efforts in walking about a room or rising from their bed are unsteady, and produced by their catenations with the immediate affections of pleasure or pain. See Section XXXIII. 1. 4.

By the above circumstances it is distinguished from madness, in which the patients well know the persons of their acquaintance, and the place where they are; and persons all the voluntary actions with steadiness and determination. See Sect.

XXXIV. 2. 2.

Delirium is fometimes less complete, and then a new face and louder voice stimulate the patient to attend to them for a few moments; and then they relapse again into perfect delirium. At other times a delirium affects but one sense, and the person thinks he sees things which do not exist; and is at the same time sensible to the questions which are asked him, and to the taste of the food which is offered to him.

This partial delirium is termed a hallucination of the difordered organ; and may probably arise from the origin of one nerve of sense being more liable to inflammation than the others; that is, an exuberance of the sensorial power of sensation may affect it; which is therefore thrown into action by slighter sensitive catenations, without being obedient to external stimulus, or

to the power of volition.

The perpetual flow of ideas in delirium is owing to the fame circumstance, as of those in our dreams; namely, to the defect or paralysis of the voluntary power; as in hemiplegia, when one side of the body is paralytic, and thus expends less of the sensorial power, the limbs on the other side are in constant motion from

the exuberance of it. Whence less sensorial power is exhausted in delirium, than at other times, as well as in sleep; and hence in severs with great debility, it is perhaps, as well as the stupor, rather a favourable circumstance; and when removed by numerous blisters, the death of the patient often follows the recovery of his understanding. See Class I. 2. 5. 6. and I. 2. 5. 10.

Delirium in diseases from inirritability is sometimes preceded

by a propenfity to furprise. See Class I. 1. 5. 12.

M. M. Fomentations of the shaved head for an hour repeatedly. A blister on the head. Rising from bed. Wine and opium, and sometimes venesection in small quantity by cupping,

if the strength of the arterial system will allow it.

- 2. Delirium maniacale. Maniacal delirium. There is another kind of delirium, described in Sect. XXXIII. 1. 4. which has the increase of pleasurable or painful sensation for its cause, without any diminution of the other sensorial powers; but as this excites the patient to the exertion of voluntary actions, for the purpose of obtaining the object of his pleasurable ideas, or avoiding the object of his painful ones, such as perpetual prayer, when it is of the religious kind; it belongs to the infanities described in Class III. 1. 2. 1. and is more properly termed hallucinatio maniacalis.
- 3. Delirium ebrietatis. The drunken delirium is in nothing different from the delirium attending fevers except in its cause, as from alcohol, or other poisons. When it is attended with an apoplectic stupor, the pulse is generally low; and venesection I believe sometimes destroys those, who would otherwise have recovered in a few hours.

M. M. Diluting liquids. An emetic.

4. Somnium. Dreams constitute the most complete kind of delirium. As in these no external irritations are attended to, and the power of volition is entirely suspended; so that the sensations of pleasure and pain, with their affociations, alone excite the endless trains of our sleeping ideas; as explained in Sect. XVIII. on sleep.

5. Hallucinatio vifus. Deception of fight. These visual hallucinations are perpetual in our dreams; and sometimes precede general delirium in severs; and sometimes belong to reverie, and to infanity. See Class III. 1. 2. 1. and 2. and must

be treated accordingly.

Other kinds of visual hallucinations occur by moon-light; when objects are not seen so distinctly as to produce the usual ideas affociated with them, but appear to us exactly as they are seen. Thus the trunk of a tree appears a flat surface, instead of

a cylinder as by day, and we are deceived and alarmed by feeing things as they really are feen. See Berkley on Vision.

6. Hallucinatio auditus. Auricular deception frequently occurs in dreams, and fometimes precedes general delirium in fevers; and fometimes belongs to vertigo, and to reverie, and to infanity. See Sect. XX. 7. and Clafs III. 1. 2. 1. and 2.

7. Rubor a calore. The blush from heat is occasioned by the increased action of the cutaneous vessels in consequence of the in-

creased sensation of heat. See Class I. 1. 2. 1. and 3.

8. Rubor jucunditatis. The blush of joy is owing to the increased action of the capillary arteries, along with that of every moving vessel in the body, from the increase of pleasurable sensation.

9. Priapismus amatorius. Amatorial priapism. The blood is poured into the cells of the corpora cavernosa much faster than it can be reabsorbed by the vena penis, owing in this case to the pleasurable sensation of love increasing the arterial action. See

Class I. 1. 4. 6.

10. Distentio manularum. The teats of female animals, when they give suck, become rigid and erected, in the same manner as in the last article, from the pleasurable fensation of the love of the mother to her offspring. Whence the teat may properly be called an organ of sense. The nipples of men do the same when rubbed with the hand. See Class I. 1. 4. 7.

ORDO II.

Decreased Sensation.

GENUS I.

Of the General System.

SPECIES.

1. Stultitia infensibilis. Folly from infensibility. The pleafure or pain generated in the system is not sufficient to promote the usual activity either of the sensual or muscular fibres.

2. Tedium vite. Ennui. Irksomeness of life. The pain of laziness has been thought by some philosophers to be that principle of action, which has excited all our industry, and distinguished mankind from the brutes of the field. It is certain that, where the ennui exists, it is relieved by the exertions of our minds or bodies, as all other painful sensations are relieved; but it depends much upon our early habits, whether we become patient of laziness, or inclined to activity, during the remainder of our lives, as other animals do not appear to be affected with this malady; which is perhaps less owing to deficiency of the pleasurable sensation, than to the superabundancy of voluntary power which occasions pain in the muscles by its accumulation; as appears from the perpetual motions of a squirrel confined in a cage.

3. Paresis sensitiva. Weakness of the whole system from in-

fensibility.

ORDO II.

Decreased Sensation.

GENUS II.

Of particular Organs.

SPECIES.

those debilitated by fermented liquors, are liable to lose their appetite for animal food; which is probably in part owing to the deficiency of gastric acid, as well as to the general decay of the system: elderly people will go on years without animal food; but inebriates soon sink, when their digestion becomes so far impaired. Want of appetite is sometimes produced by the putrid matter from many decaying teeth being perpetually mixed with the saliva, and thence affecting the organs of taste, and greatly injuring the digestion.

M. M. Fine charcoal powder diffused in warm water, held in the mouth frequently in a day, as in Class I. 1. 4. 4. or solution of alum in water. Extract the decayed teeth. An emetic. A blifter. Chalybeates. Vitriolic acid. Bile of an ox inspissated, and made into pills; 20 grains to be taken before dinner and

fupper. Opium half a grain twice a day.

All the strength we posses is ultimately derived from the food, which we are able to digest; whence a total debility of the system frequently follows the want of appetite, and of the power of digestion. Some young ladies I have observed to fall into this general debility, so as but just to be able to walk about; which I have sometimes ascribed to their voluntary fasting, when they believed themselves too plump; and who have thus lost both their health and beauty by too great abstinence, which could never be restored.

Two young ladies applied to me, who had experienced many months of great debility, and of almost total want of appetite, from another cause, which was from bathing on a warm day in a cold fountain of water, which was covered from the sun and supplied by a powerful spring; but gradually afterwards recovered their health by the use of six grains of rhubarb with one grain of opium every night for some weeks, and a bitter draught twice a day with a slight chalybeate. See Class III. 2. 1.17.

I have feen other cases of what may be termed anorexia epi-

leptica, in which a total loss of appetite, and of the power of digestion, suddenly occurred along with epileptic fits. Miss B. a girl about eighteen, apparently very healthy, and rather plump, was feized with fits, which were at first called hysterical; they occurred at the end of menstruation, and returned very frequently with total loss of appetite. She was relieved by venefection, blifters, and opiates; her strength diminished, and after some returns of the fits, she took to her bed, and has survived 15 or 20 years; she has in general eaten half a potato a day, and feldom speaks, but retains her senses, and had many years occasional returns of convulsion. I have seen two similar cases, where the anorexia, or want of appetite, was in less degree; and but just so much food could be digested, as supplied them with sufficient strength to keep from the bed or sofa for half a day. As well as I can recollect, all these patients were attended with weak pulse, and cold pale skin; and received benefit by opium, from a quarter of a grain to a grain four times a day. See Class III. 1. 1. 7. and III. 1. 2. 20. and Suppl. I. 14. 3.

2. Adipfia. Want of thirst. Several of the inferior people, as farmers' wives, have a habit of not drinking with their dinner at all, or only take a spoonful or two of ale after it. I have frequently observed these to labour under bad digestion, and debility in consequence; which I have ascribed to the too great stimulus of solid food undiluted, destroying in process of time

the irritability of the stomach.

3. Impotentia (agencia.) Impotency much feldomer happens to the male fex than sterility to the female fex. Sometimes a temporary impotence occurs from bashfulness, or the interference of some voluntary exertion in the production of an effect, which should be performed alone by pleasurable sensation.

One, who was foon to be married to a lady of fuperior condition to his own, expressed fear of not succeeding on the wedding night; he was advised to take a grain of opium before he went to bed, and to accustom himself to sleep with a woman previously, but not to enjoy her, to take off his bashfulness;

which succeeded to his wish.

Mr. John Hunter in his work on the Venereal Disease, has given an ingenious section on this subject of mental impotence, in which he relates a successful mode of treatment. He prevailed on a person in this situation to promise on his honor to pass six nights in bed with a young woman without attempting to have connection with her, whatever might be his power or inclination. He afterwards assured Mr. Hunter, that this resolution had produced such a total alteration in the state of his mind, that the power of connection soon recurred, for instead of going to bed with the

fear

fear of inability, he went with fears, that he should be possessed with too much desire, and too much power, so as to become uneasy to him, which really happened, as he would have been happy to have shortened the time; and when he had once broken the spell, his mind and powers went on together; and his mind never returned to its former state.

A gentleman about 50 years of age, who had lived too freely. as he informed me, both in respect to wine and women, complained, that his defire for the fex remained, and that he occafionally parted with femen, but with defect of a perfect tension penis, and that he had tried 20 drops of laudanum, and 20 drops of tincture of cantharides on going to bed without effect; and that as the debility or inirritability of the system in this case rather than any mental affection feemed to be a part of the cause, he was advised to stimulate the sphincter ani by the introduction of a piece of the root of ginger, as is done by the horse-dealers to sale-horses. And, however ridiculous the operation may appear, he affured me, that it succeeded; which I suppose might be owing to the sympathy between the sphincter ani and the penis; which is so often the cause of painful sensation in the former, when a stone at the neck of the bladder affects the latter; and converfely when painful piles affect the rectum, a strangury is sometimes produced by sympathy.

For restoring the venereal power M. Le Roy thinks phosphorus taken in a dose of a quarter of a grain rubbed with oil or yolk of egg, or honey; or even the acid of phosphorus, to posfels great efficacy. Med. Review, Vol. V. p. 204. The water in which phosphorus has been kept some time, probably posfesses some of this acid, and is also recommended by M. Le Roy. I ought here to add, that I have been lately informed, that a gentleman directed four grains of phosphorus to be made into pills with conferve, with defign of increasing his venereal power. He was feized with intolerable fense of heat at his ftomach, pulse feeble, but not quickened, livid countenance, foreness of his bowels to the touch, and incessant vomitings, by which he at last brought up some blood. His illness lasted five or fix days. He did not acknowledge any cause of his sudden illness, but said he was certain emetics would cure him, and took two by his own request. After his death, the apothecary mentioned his having directed the pills as above, which were made three days before he was taken ill; and he was believed to have taken about half of them.

M. M. Chalybeates. Opium. Bark. Tincture of cantharides.

^{4.} Sterilitas. Barrenness. One of the ancient medical wri-

ters afferts, that the female fex become pregnant with most certainty at or near the time of menstruation. This is not improbable, fince these monthly periods seem to resemble the monthly venereal orgafin of some female quadrupeds, which become pregnant at those times only; and hence the computation of pregnancy is not often erroneous, though taken from the last menstruation. See Section XXXVI. 2. 3.

M. M. Opium a grain every night. Chalybeates in very

fmall doses. Bark. Sea-bathing.

CLASS H. 2. 2. 5.

5. Insensibilitas artuum. As in some paralytic limbs. A great infensibility sometimes accompanies the torpor of the skin in cold fits of agues. Some parts have retained the fense of heat, but not the sense of touch. See Sect. XVI. 6.

M. M. Friction with flannel. A blifter. Warmth.

6. Dysuria insensitiva. Insensibility of the bladder. A difficulty or total inability to make water attends some fevers with great debility, owing to the infensibility or inirritability of the bladder. This is a dangerous but not always a fatal symptom. See Class III. 2. 1. 6.

M. M. Draw off the water with a catheter. Affift the patient in the exclusion of it by compressing the lower parts of the abdomen with the hands. Wine two ounces, Peruvian bark one dram in decoction, every three hours alternately. Balfam of copaiva. Oil of almonds, with as much camphor as can be diffolved in it, applied as a liniment rubbed on the region of the bladder and perinæum, and repeated every four hours, was used in this difease with success by Mr. Latham. Med. Comment. 1791, p. 213.

7. Accumulatio alvina. An accumulation of feces in the rectum, occasioned by the torpor, or infensibility, of that bowel. But as liquids pass by these accumulations, it differs from the constipatio alvi, which is owing to too great absorption of the

alimentary canal.

Old milk, and especially when boiled, is liable to induce this kind of costiveness in some grown persons; which is probably owing to their not possessing sufficient gastric acid to curdle and digest it; for as both these processes require gastric acid, it follows, that a greater quantity of it is necessary, than in the digeftion of other aliments, which do not previously require being curdled. This ill digested milk not sufficiently stimulating the rectum, remains till it becomes a too folid mass. On this account milk feldom agrees with those, who are subject to piles, by inducing costiveness and large stools.

M. M. Extract the hardened scybala by means of a marrowspoon; or by a piece of wire, or of whale-bone bent into a bow,

and introduced. Injections of oil. Castor oil, or oil of almonds, taken by the mouth. A large clyster of smoke of to-bacco. Six grains of rhubarb taken every night for many months. Aloes. An endeavour to establish a habit of evacuation at a certain hour daily. See Class I. 1. 3. 5.

AND RESIDENCE AND ADDRESS OF THE PARTY OF TH

ORDO III.

Retrograde Sensitive Motions.

GENUS I.

Of Excretory Ducts.

THE retrograde action of the cesophagus in ruminating animals, when they bring up the food from their first stomach for the purpose of a second mastication of it, may probably be caused by agreeable sensation; similar to that which induces them to swallow it both before and after this second mastication; and then this retrograde action properly belongs to this place, and is erroneously put at the head of the order of irritative retrograde motions. Class I. 3. 1. 1.

SPECIES.

1. Ureterum motus retrogressus. When a stone has advanced into the ureter from the pelvis of the kidney, it is sometimes liable to be returned by the retrograde motion of that canal, and the patient obtains fallacious ease, till the stone is again pushed into the ureter.

2. Urethra motus retrogressus. There have been instances of bougies being carried up the urethra into the bladder most probably by an inverted motion of this canal; for which some have undergone an operation similar to that for the extraction of a stone. A case is related, in some medical publication, in which a catgut bougie was carried into the bladder, and, after remaining many weeks, was voided piece-meal in a semi-dissolved state. Another case is related of a French officer, who used a leaden bougie; which at length sound its way into the bladder, and was, by injecting crude mercury, amalgamated and voided.

In the same manner the infection, from a simple gonorrhoea, is probably carried further along the course of the urethra; and small stones frequently descend some way into the urethra, and are again carried up into the bladder by the inverted action of this canal.

3. Ductus choledochi motus retrogressus. The concretions of bile, called gall-stones, frequently enter the bile-duct, and give violent pain for some hours; and return again into the gall-bladder, by the retrograde action of this duct. May not oil be carried up this duct, when a gall-stone gives great pain, by its retrograde spasmodic action? See Class I. 1. 3. 8.

M. M. Opium a grain and half.

DISEASES OF VOLITION.

ORDO I.

Increased Volition.

GENUS I.

Increased Actions of the Muscles.

WE now step forward to consider the diseases of volition, that superior faculty of the sensorium, which gives us the power of reason, and by its facility of action distinguishes mankind from brute animals; which has effected all that is great in the world, and superimposed the works of art on the situations of nature.

Pain is introduced into the fystem either by excess or defect of the action of the part. (Sect. IV. 5.) Both which circumstances seem to originate from the accumulation of sensorial power in the affected organ. Thus when the skin is exposed to great cold, the activity of the cutaneous vessels is diminished, and in consequence an accumulation of sensorial power obtains in them, because they are usually excited into incessant motion by the stimulus of heat, as explained in Sect. XII. 5. 2. Contrarywise, when the vessels of the skin are exposed to great heat, an excess of sensorial power is also produced in them, which is derived thither by the increase of stimulus above what is natural.

This accounts for the relief which is received in all kinds of pain by any violent exertions of our muscles or organs of sense; which may thus be in part ascribed to the exhaustion of the sensorial power by such exertions. But this relief is in many cases so instantaneous, that it seems nevertheless probable, that it is also in part owing to the different manner of progression of the two sensorial powers of sensation and volition; one of them commencing at some extremity of the sensorium, and being propagated towards the central parts of it; and the other commencing in the central parts of the sensorium, and being propagated towards the extremities of it; as mentioned in Sect. XI. 2. 1.

These violent voluntary exertions of our muscles or ideas to relieve the sensation of pain constitute convulsions and madness; and are distinguished from the muscular actions owing to increased sensation, as in sneezing, or coughing, or parturition, or

ejectio

ejectio feminis, because they do not contribute to dislodge the cause, but only to prevent the sensation of it. In two cases of parturition, both of young women with their first child, I have seen general convulsions occur from excess of voluntary exertion, as above described, instead of the actions of particular muscles, which ought to have been excited by sensation for the exclusion of the setus. They both became insensible, and died after some hours; from one of them the setus was extracted in vain. I have heard also of general convulsions being excited instead of the actions of the musculi acceleratores in the ejectio seminis, which terminated fatally. See Class III. 1. 1. 7.

These violent exertions are most frequently excited in confequence of those pains, which originate from defect of the action of the part. See Sect. XXXIV. 1. and 2. The pains from excess and defect of the action of the part are distinguishable from each other by the former being attended with increase of heat in the pained part, or of the whole body; while the latter not only exist without increase of heat in the pained part, but are generally attended with coldness of the ex-

tremities of the body.

As foon as these violent actions of our muscular or sensual fibres for the purpose of relieving pain cease to be exerted, the pain recurs; whence the reciprocal contraction and relaxation of the muscles in convulsion, and the intervals of madness. Otherwise these violent exertions continue, till so great a part of the sensorial power is exhausted, that no more of it is excitable by the faculty of volition; and a temporary apoplexy succeeds, with snoring as in prosound sleep; which so generally terminates epileptic sits.

When these voluntary exertions become so connected with certain disagreeable sensations, or with irritations, that the effort of the will cannot restrain them, they can no longer in common language be termed voluntary; but nevertheless belong to this class, as they are produced by excess of volition, and may still not improperly be called depraved voluntary actions. See Sect. XXXIV. 1. where many motions in common language termed involuntary are shown to depend on excess of volition.

When these exertions from excess of volition, which in common language are termed involuntary motions, either of mind or body, are perpetually exerted in weak constitutions, the pulse becomes quick; which is occasioned by the too great expenditure of the sensorial power in these unceasing modes of activity. In the same manner as in very weak people in severs, the pulse sometimes increases in frequency to 140 strokes in a minute, when the patients stand up or endeavour to walk; and subsides

to 110, when they lie down again in their beds. Whence it appears, that when a very quick pulse accompanies convulsion or infanity, it simply indicates the weakness of the patient; that is, that the expenditure of sensorial power is too great for the supply of it. But if the strength of the patient is not previously exhausted, the exertions of the muscles are attended with temporary increase of circulation, the reciprocal swellings and elongations of their bellies push forwards the arterial blood, and promote the absorption of the venous blood; whence a temporary increase of secretion and of heat, and a stronger pulse.

A correspondent acquaints me, that he finds difficulty in understanding how the convulsions of the limbs in epilepsy can be induced by voluntary exertions. This I suspect first to have arisen from the double meaning of the words "involuntary motions;" which are sometimes used for those motions, which are performed without the interference of volition, as the pulsations of the heart and arteries; and at other times for those actions, which occur, where two counter volitions oppose each other, and the stronger prevails; as in endeavouring to suppress laughter, and to stop the shudderings when exposed to cold. Thus when the poet writes,

Deteriora fequor.—

The stronger volition actuates the system, but not without the counteraction of unavailing smaller ones; which constitute deliberation.

A fecond difficulty may have arisen from the confined use of the words "to will," which in common discourse generally mean to choose after deliberation; and hence our will or volition is supposed to be always in our own power. But the will or voluntary power, acts always from motive, as explained in Sect XXXIV. 1. and in Class IV. 1. 3. 2. and III. 2. 1. 12. which motive can frequently be examined previous to action, and balanced against opposite motives, which is called deliberation; at other times the motive is so powerful as immediately to excite the sensorial power of volition into action, without a previous balancing of opposite motives, or counter volitions. The former of these volitions is exercised in the common purposes of life, and the latter in the exertions of epilepsy and infanity.

It is difficult to think without words, which however all those must do, who discover new truths by reasoning; and still more difficult, when the words in common use deceive us by their

twofold

twofold meanings, or by the inaccuracy of the ideas, which they fuggeft.

SPECIES.

1. Jactitatio. Restlessness. There is one kind of restlessness attending severs, which consists in a frequent change of posture to relieve the uneasiness of the pressure of one part of the body upon another, when the sensibility of the system, or of some parts of it, is increased by inflammation, as in the lumbago; which may sometimes be distinguished in its early stage by the incessant desire of the patient to turn himself in bed. But there is another restlessness, which approaches towards writhing or contortions of the body, which is a voluntary effort to relieve pain; and may be esteemed a slighter kind of convulsion, not totally unrestrainable by opposite or counteracting volitions.

Thus when a fquirrel is confined in a cage, he feels uneafiness from the accumulation of sensorial power, in his muscles, which were before in continual violent exertion in his habits of life; and in this situation finds relief by perpetually jumping about his cage to expend a part of this accumulated sensorial

rial power.

For the same reason those children, who are constrained to sit in some schools for hours together, are liable to acquire habits of moving some muscles of their saces, or hands, or feet, which are called tricks, to exhaust a part of the accumulated sensorial power. Hence restlessness is occasioned by increase of stimulus, or by accumulation of sensorial power.

M. M. A blifter. Opium. Warm bath. Bandage on the moving muscles. See Convulsio debilis, Class III. 1. 1. 5.

exercise.

2. Tremor febrilis. Reciprocal convultions of the fubcutaneous muscles, originating from the pain of the sense of heat, owing to desect of its usual stimulus, and consequent accumulation of sensorial power in it. The actual desiciency of heat may exist in one part of the body, and the pain of cold be felt most vividly in some other part associated with it by sensitive sympathy. So a chilness down the back is sirst attended to in ague-sits, though the disease perhaps commences with the torpor and consequent coldness of some internal viscus. But in whatever part of the system the desect of heat exists, or the sensation of it, the convulsions of the subcutaneous muscles exerted to relieve it are very general; and, if the pain is still greater, a chattering of the teeth is added, the

more fuddenly to exhaust the sensorial power, and because the

teeth are very fensible to cold.

These convulsive motions are nevertheless restrainable by violent voluntary counteraction; and as their intervals are owing to the pain of cold being for a time relieved by their exertion, they may be compared to laughter, except that there is no interval of pleasure preceding each moment of pain in this as in the latter.

M. M. See I. 2. 2. 1.

3. Clamer. Screaming from pain. The talkative animals, as dogs, and fwine, and children, forcam most, when they are in pain, and even from fear; as they have used this kind of exertion from their birth most frequently and most forcibly; and can therefore sooner exhaust the accumulation of sensorial power in the affected muscular or sensual organs by this mode of exertion; as described in Sect. XXXIV. 1. 3. This facility of relieving pain by screaming is the source of laughter, as explained below.

4. Rifus. The pleafurable fenfations, which occasion laughter, are perpetually passing into the bounds of pain; for pleafure and pain are often produced by different degrees of the same stimulus; as warmth, light, aromatic or volatile odours, become painful by their excess; and the tickling on the soles of the feet in children is a painful sensation at the very time it produces laughter. When the pleasurable ideas, which excite us to laugh, pass into pain, we use some exertion, as a scream, to relieve the pain, but soon stop it again, as we are unwilling to lose the pleasure; and thus we repeatedly begin to scream, and stop again alternately. So that in laughing there are three stages, first of pleasure, then pain, then an exertion to relieve that pain. See Sect. XXXIV. 1. 3.

Every one has been in a fituation, where fome ludicrous circumstance has excited him to laugh; and at the same time a sense of decorum has forbid the exertion of these interrupted screams; and then the pain has become so violent, as to occasion him to use some other great action, as biting his tongue, and pinching himself, in lieu of the reiterated screams which

constitute laughter.

5. Convulsio. Convulsion. When the pains from defect or excess of motion are more distressing than those already described, and are not relievable by such partial exertions, as in screaming, or laughter, more general convulsions occur; which vary perhaps according to the situation of the pained part, or to some previous associations formed by the early habits of life. When these convulsive motions bend the body forwards, they are term-

ed emprosthotonoi; when they bend it backward, they are termed opisthotonoi. They frequently succeed each other, but the episthotonoi are generally more violent; as the muscles, which erect the body, and keep it erect, are naturally in more constant

and more forcible action than their antagonists.

The causes of convulsion are very numerous, as from toothing in children, from worms or acidity in their bowels, from eruption of the distinct small-pox, and lastly, from breathing too long the air of an unventilated bed-room. Sir G. Baker. in the Transactions of the College, described this disease, and detected its cause; where many children in an orphan-house were crowded together in one chamber without a chimney, and were almost all of them affected with convulsion; in the hofpital at Dublin, many died of convulsions before the real cause was understood. See Dr. Beddoes's Guide to Self-preservation. In a large family, which I attended, where many female servants flept in one room, which they had contrived to render inacceffible to every blaft of air; I faw four who were thus feized with convulsions, and who were believed to have been affected by fympathy from the first who fell ill. They were removed into more airy apartments, but were some weeks before they all regained their perfect health.

Convultion is diftinguished from epilepsy, as the patient does not intirely lose all perception during the paroxysm. Which only shews, that a less exhaustion of sensorial power renders tolerable the pains which cause convulsion, than those which cause epilepsy. The hysteric convulsions are distinguished from those, owing to other causes, by the presence of the expectation of death, which precedes and succeeds them, and generally by a slow of pale urine; these convulsions do not constantly attend the hysteric disease, but are occasionally superinduced by the disagreeable sensation arising from the torpor or inversion of a part of the alimentary canal. Whence the convulsion of laughter is frequently sufficient to restrain these hysteric pains, which accounts for the fits of laughter frequently attendant on this

disease.

M. M. To remove the peculiar pain which excites the convultions. Venefection. An emetic. A cathartic with calomel. Warm-bath. Opium in large quantities, beginning with smaller ones. Mercurial frictions. Electricity. Cold-bath in the paroxysm; or cold aspersion. See Memoirs of Med. Society, Lon. Vol. III. p. 147. a paper by Dr. Currie.

5. Convulsion debilis. The convulsions of dying animals, as of those which are bleeding to death in the slaughter-house, are an effort to relieve painful sensation, either of the wound which

occasions

occasions their death, or of faintness from want of due distention of the blood vessels. Similar to this in a less degree is the subsultus tendinum, or starting of the tendons, in severs with debility; these actions of the muscles are too weak to move the limb, but the belly of the acting muscles is seen to swell, and the tendon to be stretched. These weak convulsions, as they are occasioned by the disagreeable sensation of faintness from inanition, are symptoms of great general debility, and thence frequently precede the general convulsions of the act of dying. See a case of convulsion of a muscle of the arm, and of the forearm, without moving the bones to which they were attached, Sect. XVII. 1. 8. See twitchings of the face, Class IV. 1. 3. 2.

6. Convulsio dolorifica. Raphania. Painful convulsion. In this disease the muscles of the arms and legs are exerted to relieve the pains left after the rheumatism in young and delicate people; it recurs once or twice a day, and has been mistaken for the chorea, or St. Vitus's dance; but differs from it, as the undue motions in that disease only occur, when the patient endeavours to exert the natural ones; are not attended with pain; and cease, when he lies down without trying to move: the chorea, or dance of St. Vitus, is often introduced by the itch, this by the

rheumatism.

It has also been improperly called nervous rheumatism; but is distinguished from rheumatism, as the pains recur by periods once or twice a day; whereas in the chronic rheumatism they only occur on moving the affected muscles. And by the warmth of a bed the pains of the chronic rheumatism are increased, as the muscles or membranes then become more sensible to the stimulus of the extraneous mucaginous material deposited under them. Whereas the pains of the raphania, or painful convulsion, commence with coldness of the part, or of the extremities. See Rheumatismus chronicus. Class I.

1. 3. 12.

The pains which accompany the contractions of the muscles in this disease, seem to arise from the too great violence of those contractions, as happens in the cramp of the calf of the leg; from which they differ in those being fixed, and these being reiterated contractions. Thus these convulsions are generally of the lower limbs, and recur at periodical times from some uneasy sensation from desect of action, like other periodic diseases; and the convulsions of the limbs relieve the original uneasy painful sensation, and then produce a greater pain from their own too vehement contractions. There is however another way of accounting for these pains, when they succeed the acute rheumatism; and that is by the coagulable lymph, which may be

Vol. II. NN left

fill unabforbed on the membranes; and which may be in too small quantity to affect them with pain in common muscular exertions, but may produce great pain, when the bellies of the muscles swell to a larger bulk in violent action.

M. M. Venesection. Calomel. Opium. Bark. One grain of calomel and one of opium for ten successive nights. A bandage spread with emplastrum de minio put tight on the affected

part.

7. Epilepsia is originally induced, like other convulsions, by a voluntary exertion to relieve some pain. This pain is most frequently about the pit of the stomach, or termination of the bileduct; and in some cases the torpor of the stomach, which probably occasioned the epileptic fits, remains afterwards, and produces a chronical anorexia; of which a case is related in Class II. 2. 2. 1. There are instances of its beginning in the heel, of which a case is published by Dr. Short, in the Med. Essays. Edinb. I once saw a child about ten years old, who frequently fell down in convulsions, as she was running about in play; on examination a wart was found on one ancle, which was ragged and instance; which was directed to be cut off, and the fits never recurred.

When epilepfy first commences, the patients are liable to utter one scream before they fall down; afterwards the convulsions so immediately follow the pain, which occasions them, that the patient does not recollect or seem sensible of the preceding pain. Thus in laughter, when it is not excessive, a person is not conscious of the pain, which so often recurs, and causes the successive screams or exertions of laughter, which give a temporary relief to it.

Epileptic fits frequently recur in fleep from the increase of fensibility at that time, explained in Sect. XVIII. 14. In two fuch cases, both of young women, one grain of opium given at night, and continued many months, had success; in one of them the opium was omitted twice at different times, and the fit recurred on both the nights. In the more violent case, described

in Sect. XVIII. 15, opium had no effect.

Epileptic fits generally commence with fetting the teeth, by which means the tongue is frequently wounded; and with rolling the eye-balls in every kind of direction; for the muscles which suspend the jaw, as well as those which move the eyes, are in perpetual motion during our waking hours; and yet continue subservient to volition; hence their more facile and forcible actions for the purpose of relieving pain by the exhaustion of sensorial power. See Section XXXIV. 1. 4.

Epileptic convulsions are not attended with the fear of death,

as in the hysteric disease, and the urine is of a straw colour. However it must be noted, that the disagreeable sensations in hysteric diseases sometimes are the cause of true epileptic con-

vulsions, of fyncope, and of madness.

The pain, which occasions some fits of epilepsy, is felt for a time in a diffant part of the fystem, as in a toe or heel; and is faid by the patient gradually to ascend to the head, before the general convulsions commence. This ascending fensation has been called aura epileptica, and is faid to have been prevented from affecting the head by a tight bandage round the limb. In this malady the pain, probably of some torpid membrane, or difeased tendon, is at first only so great as to induce slight spasms of the muscular fibres in its vicinity; which slight spasms cease on the numbness introduced by a tight bandage; when no bandage is applied, the pain gradually increases, till general convulfions are exerted to relieve it. The course of a lymphatic, as when poisonous matter is absorbed; or of a nerve, as in the fciatica, may, by the fympathy existing between their extremities and origins, give an idea of the afcent of an aura or vapour.

In difficult parturition it sometimes happens, that general convulsions are excited to relieve the pain of labour, instead of the exertions of those muscles of the abdomen and diaphragm, which ought to forward the exclusion of the child. See Class III. 1. 1. That is, instead of the particular muscular actions, which ought to be excited by sensation to remove the offending cause, general convulsions are produced by the power of volition, which still the pain, as in common epilepsy, without removing the cause; and, as the parturition is not thus promoted, the convulsions continue, till the sensorial power is totally exhausted, that is, till death. In patients afflicted with epilepsy from other causes, I have seen the most violent convulsions recur frequently during pregnancy without miscarriage; as they did not tend to

forward the exclusion of the fetus.

Pains of this kind have been called false pains by some writers on midwifery, and are directed to be relieved by an opiate, and then they say the true pains will commence. M. Daventer directs the accoucheur to attend to the os tincæ, to distinguish them from each other, which dilates with every true pain, but contracts with every false one, that is, the voluntary actions of other muscles to relieve pain are attended with those of the os uteri, as mentioned in Genus I. of this Class and Order preceding the description of the Species.

M. M. Venesection. A large dose of opium. Delivery.

The later in life epileptic fits are first experienced, the more dangerous

dangerous they may be esteemed in general; as in these cases the cause has generally been acquired by the habits of the patient, or by the decay of some part, and is thus probably in an increasing state. Whereas in children the change in the system, as they advance to puberty, sometimes removes the cause. So in toothing, sits of convulsion with stupor frequently occur, and cease when the tooth advances; but this is not to be expected in advanced life. Sir ————, about sixty years of age, had only three teeth lest in his upper jaw, a canine tooth, and one on each side of it. He was seized with epileptic sits, with pain commencing in these teeth. He was urged to have them extracted, which he delayed too long, till the sits were become habitual, and then had them extracted in vain, and in a few months sunk under the disease.

Mr. H. M. was seized with pain in the adductor muscle of the right thumb, and had epileptic convulsions in consequence; these gradually increased in strength and frequency; a bandage on the arm, drawn very tight as soon as the pain of the ball of the thumb commenced, prevented the epileptic fits, I suppose by lessening the pain by the numbness occasioned by compressing the nerve. I advised the nerves of this muscle to be cut, which was done or attempted, and was supposed for a time to have cured the disease, as I was informed. Afterwards it recurred and destroyed the patient, who might have probably been saved by the loss of a hand, which I should have advised, but was not again consulted.

I have to add, that the tic douloureux, or hemicrania idiopathica, I believe to be a difease of this kind, owing to a torpor of the extremity of some branch of a nerve, and should recommend, when the nerve cannot be bisected, to pass through it for many hours or even days, a current of galvanic electricity from Volta's pillar of zinc, and silver, and cloth moistened with

falt and water.

Mr. F—, who had lived intemperately, and had been occasionally affected with the gout, was suddenly seized with epileptic fits; the convulsions were succeeded by apoplectic snoring; from which he was, in about 20 minutes, disturbed by fresh convulsions, and had continued in this situation above sourand-twenty hours. About eight ounces of blood were then taken from him: and after having observed, that the apoplectic torpor continued about 20 minutes, I directed him to be forcibly raised up in bed, after he had thus lain about sisteen minutes, to gain an interval between the termination of the sleep, and the renovation of convulsion. In this interval he was induced to swallow forty drops of laudanum. Twenty more were given him

in the same manner in about half an hour, both which evidently shortened the convulsion fits, and the consequent stupor; he then took thirty more drops, which for the present removed the sits. He became rather infane the next day, and after about three more days lost the infanity, and recovered his usual state of health.

The case mentioned in Sect. XXVII. 2. where the patient was left after epileptic fits with a suffusion of blood beneath the tunica adjunctiva of the eye, was in almost every respect similar to the preceding, and submitted to the same treatment. Both of them suffered frequent relapses, which were relieved by the same means, and at length perished, I believe, by the epileptic fits.

In those patients, who have not been subject to epilepsy before they have arrived to about forty years of age, and who have been intemperate in respect to spirituous potation, I have been induced to believe, that the fits were occasioned by the pain of a diseased liver; and this became more probable in one of the above subjects, who had used means to repel eruptions on the face; and thus by some stimulant application had prevented an inflammation taking place on the fkin of the face inflead of on some part of the liver. Secondly, as in these cases infanity had repeatedly occurred, which could not be traced from an hereditary fource; there is reason to believe, that this as well as the epileptic convultions were caused by spirituous potation; and that this therefore is the original fource both of epilepfy and of infanity in those families, which are afflicted with them. This idea however brings fome confolation with it; as it may be inferred, that in a few fober generations these diseases may be eradicated, which otherwise destroy the family.

M. M. Venesection. Opium. Bark. Steel. Arsenic. Opium one grain twice a day for years together. See the pre-

ceding article, and the fucceeding one.

Anorexia epileptica, as mentioned in Class II. 2. 2. 1. is a dreadful disease, originating, I believe, from a paralysis of the stomach, and generally occasioned by the application of great external cold to the skin. A young lady, whom I saw yesterday, who had long experienced a weak state of health, went to church on an uncommonly cold Sunday, when the thermometer was said to stand below 20 during the whole day. She became immediately indisposed, and was seized in a day or two with tremors and convulsions in her sleep; and which returned every two or three days. Her extremities are now always uncommonly cold, and her appetite to food totally desective. She took three drops of a faturated solution of arsenic and a bitter draught twice a day for a fortnight, and gradually recovered her former state of health.

An other

Another young lady, whom I lately faw, began to ftart fomewhat like a violent hiccough many times in an hour, after using a very cold shower-bath repeatedly. This had continued daily at uncertain times for many months, and received temporary advantage from one drop of oil of cinnamon, three or four times a day, on powdered sugar; this case belongs to convulsion rather than epilepsy, but was attended, like the former, with great defect of appetite. In both these cases I suspect, that the great torpor of the stomach was caused by too violent or too long continued coldness applied to the skin; whence the sensorial power of association, which ought to have been excited by the action of the cutaneous vessels, and to have then contributed to the action of the stomach, did not exist; and that the stomach in consequence became torpid. See Suppl. I. 14. 3. and Art. IV. 2. 6. 8. and Class III. 2. 1. 17.

Dr. Wilson, of Spalding, has lately much recommended the argentum nitratum in epilepsy; he gives two grains and a half three times a day, mixed with bread crumbs into pills, as he afferts, with the happiest success. Annals of Medicine, 1797.

8. Epilepsia delorifica. Painful epilepsy. In the common epilepsy the convulsions are immediately induced, as soon as the disagreeable sensation, which causes them, commences; but in this the pain continues long with cold extremities, gradually increasing for two or three hours, till at length convulsions or madness come on; which terminate the daily paroxysm, and cease themselves in a little time afterwards.

This difease sometimes originates from a pain about the lower edge of the liver, sometimes in the temple, and sometimes in the pudendum; it recurs daily for five or fix weeks, and then ceases for several months. The pain is owing to defect of action, that is, to the accumulation of sensorial power in the part, which probably sympathizes with some other part, as explained in Sect. XXXV. 2. XII. 5. 3. and Class II. 1. 1. 11. and IV. 2. 2. 3.

It is the most painful malady that human nature is liable to !-

See Sect. XXXIV. 1. 4.

Mrs. C—— was feized every day about the same hour with violent pain on the right side of her bowels about the situation of the lower edge of the liver, without sever, which increased for an hour or two, till it became totally intolerable. After violent screaming she fell into convulsions, which terminated sometimes in fainting, with or without stertor, as in common epilepsy; at other times a temporary infanity supervened; which continued about half an hour, and the sit ceased. These paroxysms had returned daily for two or three weeks, and were at length removed by large doses of opium, like the sits of re-

verie or fomnambulation. About half an hour before the expected return of the fit three or four grains of opium were exhibited, and then tincture of opium was given in warm brandy and water about twenty or thirty drops every half hour, till the eyes became fomewhat inflamed, and the nofe began to itch, and by the sharp movements of the patient, or quick speech, an evident intoxication appeared; and then it generally happened that the pain ceased. But the effects of this large dose of opium was succeeded by perpetual sickness and efforts to vomit, with

great general debility all the fucceeding day. The rationale of this temporary cure from the exhibition of opium and vinous spirit depends on the great expenditure of fenforial power in the increased actions of all the irritative motions, by the stimulus of such large quantities of opium and vinous spirit; together with the production of much sensation, and many movements of the organs of fense or ideas in confequence of that fensation; and lastly, even the motions of the arterial system become accelerated by this degree of intoxication, all which foon exhausted so much sensorial power as to relieve the pain; which would otherwise have caused convulsions or infanity, which are other means of expending fenforial power. The general debility on the fucceeding day, and the particular debility of the stomach, attended in consequence with sickness and frequent efforts to vomit, were occasioned by the syltem having previously been fo strongly stimulated, and those parts in particular on which the opium and wine more immediately acted. This fickness continued so many hours as to break the catenation of motions, which had daily reproduced the paroxysm; and thus it generally happened, that the whole disease ceased for some weeks or months from one great intoxication, a circumstance not easily to be explained on any other theory.

The excess or defect of motion in any part of the system occasions the production of pain in that part, as in Sect. XII. 1. 6. This defect or excess of sibrous action is generally induced by excess or defect of the stimulus of objects external to the moving organ. But there is another source of excessive sibrous action, and consequent pain, which is from excess of volition, which is liable to affect those muscles, that have weak antagonists; as those which support the under jaw, and close the mouth in biting, and those of the calf of the leg; which are thus liable to fixed or painful contractions, as in trismus, or locked jaw, and in the cramp of the calf of the leg; and perhaps in some colics, as in that of Japan: these pains, from contraction arising from excess of volition in the part from the want of the counteraction

of antagonist musteles, may give occasional cause to epileptic sits, and may be relieved in the same way, either by exciting irritative and sensitive motions by the stimulus of opium and wine; or by convulsions or infanity, as described above, which are only different methods of exhausting the general quantity of sensori-

al power.

Confidering the great refemblance between this kind of painful epilepfy and the colic of Japan, as described by Kæmpfer; and that that difease was said to be cured by acupuncture, or the prick of a needle; I directed some very thin steel needles to be. made about three inches long, and of fuch a temper, that they would bend double rather than break; and wrapped wax thread over about half an inch of the blunt end for a handle. One of thefe needles, when the pain occurred, was pushed about an inch into the painful part, and the pain instantly ceased; but I was not certain, whether the fear of the patient, or the stimulus of the puncture, occasioned the cessation of pain; and as the paroxysm had continued some weeks, and was then declining, the experiment was not tried again. The disease is said to be very frequent in Japan, and its feat to be in the bowels, and that the acupuncture eliminates the air, which is supposed to distend the bowel. But though the aperture thus made is too small to admit of the eduction of air; yet as the stimulus of so small a puncture may either excite a torpid part into action, or cause a spasmodic one to cease to act; and lastly, as no injury could be likely to enfue from fo fmall a perforation, I should be inclined at some future time to give this a fairer trial in similar circumstances.

Another thing worth trial at the commencement of this deplorable disease would be electricity, by passing strong shocks through the painful part; which, whether the pain was owing to the inaction of that part, or of some other membrane associated with it, might stimulate them into exertion; or into inac-

tivity, if owing to fixed painful contraction.

And lastly, the cold bath, or aspersions with cold water on the affected part, according to the method of Dr. Currie in the Memoirs of a Med. Soc. London, Vol. III. p. 147, might produce great effect at the commencement of the pain. Nevertheless opium duly administered, so as to precede the expected paroxysim, and in such doses, given by degrees, as to induce intoxication, is principally to be depended upon in this deplorable malady. To which should be added, that if venesection can be previously performed, even to but sew ounces, the effect of the opium is much more certain; and still more so, if there be time to premise a brisk cathartic, or even an emetic. The effect of increas-

ed stimulus is fo much greater after previous defect of stimulus; and this is still of greater advantage, where the cause of the difease happens to confist in a material, which can be absorbed. See Art. IV. 2. 8.

M. M. Venesection. An emetic. A cathartic. Warm bath. Opium a grain every half hour. Wine. Spirit of wine. If the patient becomes intoxicated by the above means, the fit ceases, and violent vomitings and debility succeed on the subsequent day, and prevent a return. Blifters or finapifms on the fmall of the leg, taken off when they give much pain, are of use in flighter convulsions. Acupuncture. Electricity. Asperfion with cold water on the painful part. A bag of snow or ice

applied on the pained part.

o. Somnambulismus. Sleep-walking is a part of reverie, or studium inane, described in Sect. XIX. In this malady the patients have only the general appearance of being afleep in respect to their inattention to the stimulus of external objects, but, like the epilepfies above described, it consists in voluntary exertions to relieve pain. The muscles are subservient to the will, as appears by the patient's walking about, and fometimes doing the common offices of life. The ideas of the mind also are obedient to the will, because the patient's discourse is consistent, though he answers imaginary questions. The irritative ideas of external objects continue in this malady, because the patients do not run against the furniture of the room; and when they apply their volition to their organs of sense, they become sensible of the objects they attend to, but not otherwife, as general fenfation is destroyed by the violence of their voluntary exertions. At the same time the sensations of pleasure in consequence of ideas excited by volition are vividly experienced, and other ideas feem to be excited by these pleasurable tensations, as appears in the case of Master A. Sect. XXXIV. 3. 1. where a history of a hunting scene was voluntarily recalled, with all the pleasurable ideas which attended it. In melancholy madness the patient is employed in voluntarily exciting one idea, with those which are connected with it by voluntary affociations only, but not so violently as to exclude the stimuli of external objects. In reverie variety of ideas are occasionally excited by volition, and those which are connected with them either by fensitive or voluntary affociations, and that so violently as to exclude the stimuli of external objects. These two situations of our sensual motions, or ideas, relemble convulsion and epilepfy; as in the former the Aimulus of external objects is still perceived, but not in the latter. Whence this difease, so far from being connected with fleep, though it has by univerfal militake acquired its name from VOL. II.

Oa

it, arises from excess of volition, and not from a suspension of it; and though, like other kinds of epilepsy, it often attacks the patients in their sleep, yet those two, whom I saw, were more frequently seized with it while awake, the sleep-walking being a part of the reverie. See Sect. XIX. and XXXIV. 3. and Class II. 1. 7. 4. and III. 1. 2. 18.

M. M. Opium in large doses before the expected paroxysm. 10. Ashma convulsivum. The fits of convulsive ashma return at periods, and are attended with cold extremities, and so far resemble the access of an intermittent sever; but, as the lungs are not sensible to the pain of cold, a shivering does not succeed, but instead of it violent efforts of respiration; which have no tendency, as in the humoral ashma, to dislodge any offending material, but only to relieve the pain by exertion, like the shuddering in the beginning of ague-fits, as explained Class III. 1. 1. 2.

The infensibility of the lungs to cold is observable on going into frosty air from a warm room; the hands and face become painfully cold, but no such sensation is excited in the lungs; which is another argument in favour of the existence of a peculiar set of nerves for the purpose of perceiving the universal sluid matter of heat, in which all things are immersed. See Sect. XIV. 6. Yet are the lungs nevertheless very sensible to the deficiency of oxygen in the atmosphere, as all people experience, when they go into a room crowded with company and candles, and complain, that it is so close, they can scarcely breathe; and

the fame in some hot days in summer.

There are two diseases, which bear the name of asthma. The first is the torpor or inability of the minute vessels of the lungs, consisting of the terminations of the pulmonary and bronchial arteries and veins, and their attendant lymphatics; in this circumstance it resembles the dissiculty of breathing, which attends cold bathing. If this continues long, a congestion of sluid in the air-cells succeeds, as the absorbent actions cease completely before the secenting ones; as explained in Class I. 1. 2. 3. And the coldness, which attends the inaction of these vessels, prevents the usual quantity of exhalation. Some sits cease before this congestion takes place, and in them no violent sweating nor any exputition of phlegm occurs. This is the humoral asthma, described at Class II. 1. 1. 7.

The fecond kind of afthma confifts in the convulive actions in confequence of the difagreeable fenfations thus induced; which in some fits of afthma are very great, as appears in the violent efforts to raise the ribs, and to depress the diaphragm, by lifting the shoulders. These, so long as they contribute to

remove the cause of the disease, are not properly convulsions, but exertions immediately caused by sensation; but in this kind of asthma they are only efforts to relieve pain, and are frequent-

ly preceded by other epileptic convultions.

These two kinds of asthma have so many resembling features, and are so frequently intermixed, that it often requires great attention to distinguish them; but as one of them is allied to anafarca, and the other to epilepfy, we shall acquire a clearer idea of them by comparing them with those disorders. A criterion of the humoral or hydropic afthma is, that it is relieved by copious fweats about the head and breast, which are to be ascribed to the fensitive exertions of the pulmonary vessels to relieve the pain occasioned by the anafarcous congestion in the air-cells; and which is effected by the increased absorption of the mucus, and its elimination by the retrograde action of those lymphatics of the skin, the branches of which communicate with the pulmonary ones; and which partial sweats do not easily admit of any other explanation. See Class I. 3. 2.8. Another criterion of it is, that it is generally attended with fwelled legs, or other fymptoms of anafarca. A criterion of the convultive althma may be had from the absence of these cold clammy sweats of the upper part of the body only, and from the patient having occasionally been subject to convulsions of the limbs, as in the common epilepfy.

It may thus frequently happen, that in the humoral afthma fome exertions of the lungs may occur, which may not contribute to discharge the anasarcous lymph, but may be efforts simply to relieve pain; besides those efforts, which produce the increated absorption and elimination of it; and thus we have a bodily disease resembling in this circumstance the reverie, in which both sensitive and voluntary motions are at the same time, or in

fuccession, excited for the purpose of relieving pain.

It may likewise sometimes happen, that the disagreeable senfation, occasioned by the congestion of lymph in the air-cells in the humoral or hydropic asthma, may induce voluntary convulsions of the respiratory organs only to relieve the pain, without any sensitive actions of the pulmonary absorbents to absorb and eliminate the congestion of serous sluid; and thus the same cause may occasionally induce either the humoral or convulsive asthma.

The humoral afthma has but one remote cause, which is the torpor of the pulmonary vessels, like that which occurs on going into the cold bath; or the want of absorption of the pulmonary lymphatics to take up the lymph effused into the air-cells. Whereas the convulsive asthma, like other convulsions, or epi-

lepfies.

lepsies, may be occasioned by pain in almost any remote part of the system. But in some of the adult patients in this disease, as in many epilepsies, I have suspected the remote cause to be a

pain of the liver, or of the biliary ducts.

The afthmas, which have been induced in confequence of the recess of eruptions, especially of the leprous kind, countenance this opinion. One lady I knew, who for many years laboured under an asthma, which ceased on her being afflicted with pain, swelling, and distortion of some of her large joints, which were esteemed gouty, but perhaps erroneously. And a young man, whom I saw yesterday, was seized with asthma on the retrocession, or ceasing of eruptions on his sace.

The convultive attorna, as well as the hydropic, is more liable to return in hot weather; which may be occasioned by the less quantity of oxagen existing in a given quantity of warm air, than of cold, which can be taken into the lungs at one inspiration. They are both most liable to occur after the first sleep, which is therefore a general criterion of asthma. The cause of this is explained in Sect. XVIII. 15. and applies to both of them, as our sensibility to internal uneasy sensation increases

during fleep.

When children are gaining teeth, long before they appear, the pain of the gums often induces convulfions. This pain is relieved in some by sobbing and screaming; but in others a laborious respiration is exerted to relieve the pain; and this constitutes the true asthma convulsivum. In other children again general convulsions, or epileptic paroxysms, are induced for this purpose; which, like other epilepsies, become established by habit, and recur before the irritation has time to produce the painful sensation, which originally caused them.

The afthma convultivum is also fometimes induced by worms, or by acidity in the stomachs of children, and by other painful fensarions in adults; in whom it is generally called nervous afthma, and is often joined with other epileptic symptoms.

This afthma is distinguished from the peripneumony, and from the croup, by the presence of sever in the two latter. It is distinguished from the humoral asthma, as in that the patients are more liable to run to the cold air for relief, are more subject to cold extremities, and experience the returns of it more frequently after their first sleep. It is distinguished from the hydrops thoracis, as that has no intervals, and the patient sits constantly upright, and the breath is colder; and, where the pericardium is affected, the pulse is quick and unequal. See Hydrops Thoracis, L. 2. 3. 14.

M. M. Venfection once. A cathartic with calomel once.

Opium. Afafœtida. Warm bath. If the cause can be detected, as in toothing or worms, it should be removed. As this species of asthma is so liable to recur during sleep, like epileptic fits, as mentioned in Section XVIII. 15 there was reason to believe, that the respiration of an atmosphere mixed with hydrogen, or any other innocuous air, which might dilute the oxygen, would be useful in preventing the paroxysms by decreasing the sensibility of the system. This, I am informed by Dr. Beddoes, has been used with decided success by Dr. Ferriar. See Class II. 15 17.

as first described by Dr. Heberden in the Transactions of the College; its principal symptoms consist in a pain about the middle of the sternum, or rather lower, on every increase of pulmonary or muscular exertion, as in walking safter than usual, or going quick up a hill, or even up stairs; with great dissibly of breathing, so as to occasion the patient instantly to stop. A pain in the arms about the insertion of the tendon of the pectoral muscle generally attends, and a desire of resting by hanging on a door or branch of a tree by the arms is sometimes observed. Which is explained in Class I. 2. 3. 14. and in Sect. XXIX. 5. 2.

These patients generally die suddenly; and on examining the thorax no certain cause, or seat, of the disease has been detected; some have supposed the valves of the arteries, or of the heart, were impersect; and others that the accumulation of sat about this viscus or the lungs obstructed their due action; but other observations do not accord with these suppositions.

Mr. W——, an elderly gentleman, was seized with asthma during the hot part of last summer; he always waked from his sirst sleep with dissicult respiration, and pain in the middle of his sternum, and after about an hour was enabled to sleep again. As this had returned for about a fortnight, it appeared to me to be an asthma complicated with the disease, which Dr. Heberden has called angina pectoris. It was treated by venesection, a cathartic, and then by a grain of opium given at going to bed, with ether and tincture of opium when the pain or asthma recurred, and lastly with the bark, but was several days before it was perfectly subdued.

This led me to conceive, that in this painful afthma the diaphragm, as well as the other muscles of respiration, was thrown into convulsive action, and that the fibres of this muscle not having proper antagonists, a painful fixed spasm of it, like that of the muscles in the calf of the leg in the cramp, might be the cause of death in the angina pectoris, which I have thence ar-

ranged under the name of painful afthma, and leave for further

investigation.

From the history of the case of the late much lamented John Hunter, and from the appearances after death, the case seems to have been of this kind, complicated with vertigo and consequent affection of the stomach. The remote cause seems to have arisen from offsications of the coronary arteries; and the immediate cause of his death from fixed spasm of the heart. Other histories and diffections are still required to put this matter out of doubt; as it is possible, that either a fixed spasm of the diaphragm, or of the heart, which are both surnished with but weak antagonists, may occasion sudden death; and these may constitute two distinct diseases.

Four patients I have now in my recollection, all of whom I believed to labour under the angina pectoris in a great degree; which have all recovered, and have continued well three or four years by the use, as I believe, of issues on the inside of each thigh; which were at first large enough to contain two pease each, and afterwards but one. They took besides some slight antimonial medicine for a while, and were reduced to half the quantity or strength of their usual potation of fermented liquor.

The use of semoral issues in angina pectoris was first recommended by Dr. Macbride, physician at Dublin, Med. Observ. and Enquir. Vol. VI. And I was further induced to make trial of them, not only because the means which I had before used were inadequate, but from the ill effect I once observed upon the lungs, which succeeded the cure of a small fore beneath the knee; and argued conversely, that issues in the lower limbs

might affift a difficult respiration.

Mrs. L—, about fifty, had a small fore place, about the size of half a pea on the inside of the leg a little below the knee. It had discharged a pellucid sluid, which she called a ley-water, daily for fourteen years, with a great deal of pain; on which account she applied to a surgeon, who, by means of bandage and a faturnine application, soon healed the fore, unheedful of the consequences. In less than two months after this I saw her with great difficulty of breathing, which with universal anasarca soon destroyed her.

The theory of the double effect of iffues, as above related, one in relieving by their presence the asthma dolorificum, and the other in producing by its cure an anasarca of the lungs, is not easy to explain. Some similar effects from cutaneous eruptions and from blisters are mentioned in Class I. 1. 2. 9. In these cases it seems probable, that the pain occasioned by issues, and perhaps the absorption of a small quantity of aerated puru-

lent matter, stimulate the whole system into greater energy of action, and thus prevent the torpor which is the beginning of so many diseases. In confirmation of this effect of pain on the system, I remember the case of a lady of an ingenious and active mind, who, for many of the latter years of her life, was perpetually subject to great pains of her head from decaying teeth. When all her teeth were gone, she became quite low spirited, and melancholy in the popular sense of that word, and after a year or two became universally dropsical and died.

M. M. Issues in the thighs. Five grains of rhubarb, and one fixth of a grain of emetic tartar every night for some months, with or without half a grain of opium. No stronger liquor than small beer or wine diluted with twice its quantity of water. Since I wrote the above I have seen two cases of hydrops thoracis attended with pain in the left arm, so as to be mistaken for asthma dolorisicum, in which semoral issues, though applied

early in the difease, had no effect.

12. Stridor dentium. The clattering of the teeth on going into cold water, or in the beginning of ague-fits, is an exertion along with the tremblings of the skin to relieve the pain of cold. The teeth and skin being more sensible to cold than the more internal parts, and more exposed to it, is the reason that the muscles which serve them, are thrown into exertion from the pain of cold rather than those of respiration, as in screaming from more acute pain. Thus the poet,

Put but your toes into cold water, Your correspondent teeth will clatter.

PRIOR.

In more acute pains the jaws are gnashed together with great vehemence, insomuch that sometimes the teeth are said to have been broken by the force. See Sect. XXXIV. 1. 3. In these cases something should be offered to the patient to bite, as a towel, otherwise they are liable to tear their own arms, or to bite their attendants, as I have witnessed in the painful epi-

lepfy.

13. Tetanus trifmus. Cramp. The tetanus confifts of a fixed fpasm of almost all the muscles of the body; but the trismus, or locked jaw, is the most frequent disease of this kind. It is generally believed to arise from sympathy with an injured tendon. In one case where it occurred in consequence of a broken ancle from a fall from a horse, it was preceded by evident hydrophobia. Amputation was advised but not submitted to; two wounds were laid into one with scissors, but the patient died about the seventh day from the accident. In this case the

wounded

wounded tendon, like the wounds from the bite of a mad dog, did not produce the hydrophobia, and then the locked jaw, till feveral days after the accident.

I twice witnessed the locked jaw from a pain beneath the sternum, about the part where it is complained of in painful asthma, or angina pectoris, in the same lady at some years distance of time. The last time it had continued two days, and she wrote her mind, or expressed herself by signs. On observing a broken tooth, which made a small aperture into her mouth, I rolled up five grains of opium like a worm about an inch long, and introducing it over the broken tooth, pushed it onward by means of a small crow-quill; as it dissolved I observed she swallowed her saliva, and in less than half an hour she opened her mouth and conversed as usual.

Men are taught to be ashamed of screaming from pain in their early years; hence they are prone to exert the muscles of the jaws instead, which they have learnt to exert frequently and violently from their insancy; whence the locked jaw. This and the following spasm have no alternative relaxations, like the preceding ones; which is perhaps owing, first, to the weakness of their antagonist muscles, those which elevate the jaw being very strong for the purpose of biting and masticating hard substances, and for supporting the under jaw, with very weak antagonist muscles; and secondly, to their not giving sufficient relief even for a moment to the pain, or its preceding irritation, which excited them.

M. M. Opium in very large quantities. Mercurial ointment used extensively. Electricity. Cold bath. Dilate the wound, and fill it with lint moillened with spirit of turpentine; which inflames the wound, and cures or prevents the convulsions. See a case, Transact. of American Society, Vol. II. p. 227.

Wine in large quartities in one case was more successful than opium; it probably inflames more, which in this disease is desirable. Between two or three ounces of bark, and from a quart to three pints of wine a day, succeeded better than opi-

um. Ib.

14. Tetanus dolorificus. Painful cramp. This kind of fpafm most frequently attacks the calf of the leg, or muscles of the toes; it often precedes paroxysms of gout, and appears towards the end of violent diarrhoza, and from indigestion, or from acid dist. In these cases it seems to sympathize with the bowels, but is also frequently produced by the pain of external cold, and by the too great previous extension of the muscles, whence some people get the cramp in the extensor muscles of the toes after walking

walking down hill, and of those of the calf of the leg after walking up a steep eminence. For the reason why these cramps

commence in fleep, see Sect. XVIII, 15.

The muscle in this disease contracts itself to relieve some fmaller pain, either from irritation or affociation, and then falls into great pain itself, from the too great action of its own fibres. Hence any muscle, by being too vehemently exerted, falls into cramp, as in fwimming too forcibly in water, which is painfully cold; and a fecondary pain is then induced by the too violent contraction of the muscle; though the pain, which was the cause of the contraction, ceases. Which accounts for the continuance of the contraction, and diftinguishes this disease from other convulsions, which are relaxed and exerted alternately. Hence whatever may be the cause of the primary pain, which occasions the cramp of the calf of the leg, the secondary one is relievable by standing up, and thus by the weight of the body on the toes forcibly extending the contracted muscles. For the cause which induces these muscles of the calf of the leg to fall into more violent contraction than other spasmodic muscles, proceeds from the weakness of their antagonist muscles; as they are generally extended again after action by the weight of the body on the balls of the toes. See the preceding article.

M. M. Rub the legs with camphor diffolved in oil, and let the patient wear stockings in bed. If a foot-board be put at the bed's feet, and the bed be so inclined, that he will rest a little with his toes against the foot-board, that pressure is said to prevent the undue contractions of the musculi gastrocnemii, which constitute the calf of the leg. In gouty patients, or where the bowels are affected with acidity, half a grain of opium, and six grains of rhubarb, and six of chalk, every night. Flesh-meat for supper. A little very weak warm spirit and water may be taken for present relief, when these cramps are

very troublesome to weak or gouty patients.

15. Hydrophobia. Dread of water generally attending canine madnefs. I was witnefs to a case, where this disease preceded the locked jaw from a wound in the ancle, occasioned by a fall from a horse; as mentioned in the preceding article. It came on about the sixth day after the accident; when the patient attempted to swallow sluids, he became convulsed all over from the pain of this attempt, and spurted them out of his mouth with violence. It is also said to happen in some hysterical cases. Hence it seems rather the immediate consequence of a pained tendon, than of a contagious poison. And is so far analogous to tetanus, according with the opinions of Dr. Rush and Dr. Percival.

Vol. II.

In other respects, as it is produced by the saliva of an enraged animal instilled into a wound, it would seem analogous to the poison of venomous animals. And from the manner of its access so long after the bite, and of its termination in a short time, it would seem to resemble the progress of contagious severs. See Sect. XXII. 3. 3.

If the patient was bitten in a part, which could be totally cut away, as a finger, even after the hydrophobia appears, it is probable it might cure it; as I suspect the cause still remains in the wounded tendon, and not in a diffused insection tainting the blood. Hence there are generally uneasy sensations, as cold or numbress, in the old cicatrix, before the hydrophobia commences. See a case in Medical Communications, Vol. II. p. 190.

If the diseased tendon could be inflamed without cutting it out, as by cupping, or caustic, or blister after cupping, and this in the old wound long since healed, after the hydrophobia commences, it might prevent the spasms about the throat. As inflaming the teeth by the use of mercury is of use in some kinds of hemicrania. Put spirit of turpentine on the wound, wash it

well. See Class I. 3. 1. 11. IV. 1. 2. 7.

M. M. Wine, musk, oil, internally. Opium, mercurial ointment, used extensively. Mercurial fumigation. Turpeth mineral. To salivate the patient as soon as possible. Exsection or a caustic on the scar, even after the appearance of hydrophobia. Put a tight bandage on the limb above the scar of the old wound to benumb the pained tendon, however long the wound may have been healed. Could a hollow catheter of elastic gum, caoutchouc, be introduced into the essophagus by the mouth or nostril, and liquid nourishment be thus conveyed into the stomach? See Desault's Journal, Case I. where in an ulcer of the mouth, such a catheter was introduced by the nostril, and kept in the essophagus for a month, by which means the patient was nourished and preserved.

It is recommended by Dr. Bardsley to give oil internally by a similar method contrived by Mr. John Hunter. He covered a probang with the skin of a small eel, or the gut of a lamb or cat. It was tied up at one end above and below the sponge, and a slit made above the upper ligature; to the other end of the eel skin or gut was fixed a bladder and pipe. The probang thus covered was introduced into the stomach, and the liquid food or medicine was put into the bladder and squeezed down through the cel-skin. Mem. of Society at Manchester. See Class I. 2. 3. 25.

Dr. Bardsley has endeavoured to prove, that dogs never experience the hydrophobia, or canine madness, without having been previously bitten or insected; and secondly, that the disease

ease in this species of animal always shews itself in five or six weeks; and concludes from hence, that this dreadful malady might be annihilated by making all the dogs in Great Britain perform a kind of quarantine, by shutting them up for a certain number of weeks. Though the disease from the bite of the mad dog is perhaps more analogous to those from the wounds inslicted by venomous animals than to those from other contagious matter, yet these observations are well worthy further attention; which the author promises.

In Dr. Hamilton's elaborate treatife on hydrophobia, Longman, London, it is proposed to try the effect of arsenic in this disease, which is said to be the principal ingredient of the Tanjore pill, which is said to cure those who are diseased by the bite of

ferpents, and to cure the hydrophobia.

A folution of fublimate of mercury in rectified spirits is also worthy a trial, as mentioned in Class I. 3. 1. 11.

.

ORDO I.

Increased Volition.

GENUS II.

With increased Actions of the Organs of Sense.

In every fpecies of madness there is a peculiar idea either of desire or aversion, which is perpetually excited in the mind with all its connections. In some constitutions this is connected with pleasurable ideas without the exertion of much muscular action, in others it produces violent muscular action to gain or avoid the object of it, in others it is attended with despair and inaction. Mania is the general word for the two former of these, and melancholia for the latter; but the species of them are as numerous as the desires and aversions of mankind.

In the present age the pleasurable infanities are most frequently induced by superstitious hopes of Heaven, by sentimental love, and by personal vanity. The surious infanities by pride, anger, revenge, suspicion. And the melancholy ones by fear of poverty, sear of death, and fear of Hell; with innumer-

able others.

Quicquid agunt homines, votum, timor, ira, voluptas, Gaudia, difcurfus, nostri est farrago libelli.

JUVEN. I. 85.

This idea, however, which induces madness or melancholy, is generally untrue; that is, the object is a mistaken fact. As when a patient is perfuaded he has the itch, or venereal disease, of which he has no fymptom, and becomes mad from the pain this idea occasions. So that the object of madness is generally a delirious idea, and thence cannot be conquered by reason; because it continues to be excited by painful sensation, which is a thronger stimulus than volition. Most frequently pain of body is the cause of convulsion, which is often however exchanged for madness; and a painful delirious idea is most frequently the cause of madness originally, but sometimes of convulsion. Thus I have feen a young lady become convulfed from a fright, and die in a few days; and a temporary madness frequently terminates the paroxysms of the epilepsia dolorifica, and an infanity of greater permanence is frequently induced by the pains or bruifes of parturition.

Where the patient is debilitated a quick pulse sometimes at-

tends

tends insane people, which is nevertheless generally only a symptom of the debility owing to the too great expenditure of sensorial power; or of the paucity of its production, as in irritative, or insensitive inirritated fever. See Class III. 1.

But nevertheless where the quick pulse is permanent, it shews the presence of sever; and as the madness then generally arises from the disagreeable sensations attending the sever, it is so far a good symptom; because when the sever is cured, or ceases spontaneously, the infanity most frequently vanishes at the same time.

The stimulus of so much volition supports infane people under variety of hardships, and contributes to the cure of diseases from debility, as sometimes occurs towards the end of severs. See Sect. XXXIV. 2. 5. And, on the same account, they bear large doses of medicines to procure any operation on them; as emetics, and cathartics, which, before they produce their effect in inverting the motions of the stomach in vomiting, or of the absorbents of the bowels in purging, must first weaken the natural actions of those organs, as shewn in Sect. XXXV. 1. 13.

From these considerations it appears, that the indications of cure must consist in removing the cause of the pain, whether it arises from a delirious idea, or from a real fact, or from bodily disease; or secondly, if this cannot be done, by relieving the pain in consequence of such idea or disease. The first is sometimes effected by presenting frequently in a day contrary ideas to shew the fallacy, or the too great estimation, of the painful ideas. 2dly. By change of place, and thus presenting the stimulus of new objects, as a long journey. 3dly. By producing forgetfulness of the idea or object, which causes their pain; by removing all things which recal it to their minds; and avoiding all conversation on similar subjects. For I suppose no disease of the mind is so perfectly cured by other means as by forgetfulness.

Secondly, the pain in confequence of the ideas or bodily difcases above described is to be removed, first, by evacuations, as venesection, emetics, and cathartics; and then by large doses of opium, or by the vertigo occasioned by a circulating swing, or by a sea-voyage, which, as they affect the organs of sense as well as evacuate the stomach, may contribute to answer both indications of cure.

Where maniacs are outrageous, there can be no doubt but coercion is necessary; which may be done by means of a strait waistcoat; which disarms them without hurting them; and by tying a handkerchief round their ankles to prevent their escape. In others there can be no doubt, but that confinement retards

rather than promotes their cure; which is forwarded by change of ideas in confequence of change of place and of objects, as by

travelling or failing.

The circumstances which render confinement necessary, are first, if the lunatic is liable to injure others, which must be judged of by the outrage he has already committed. 2dly. If he is likely to injure himself; this also must be judged of by the despondency of his mind, if such exists. 3dly. If he cannot take care of his affairs. Where none of these circumstances exist, there should be no confinement. For though the mistaken idea continues to exist, yet if no actions are produced in consequence of it, the patient cannot be called insane. He can only be termed delirious. If every one, who possesses mistaken ideas, or who puts false estimates on things, was liable to confinement, I know not who of my readers might not tremble at the sight of a madhouse!

The most convenient distribution of infanities will be into general, as mania mutabilis, studium inane, and vigilia; and into partial infanities. These last again may be subdivided into defires and aversions, many of which are succeeded by pleasurable or painful ideas, by fury or dejection, according to the degree or violence of their exertions. Hence the analogy between the infanities of the mind, and the convultions of the mufeles described in the preceding genus, is curiously exact. The convulfions without stupor, are either just sufficient to obliterate the pain, which occasions them; or are succeeded by greater pain, as in the convulsio dolorifica. So the exertions in the mania mutabilis are either just sufficient to allay the pain which occafions them, and the patient dwells comparatively in a quiet flate; or those exertions excite painful ideas, which are succeeded by furious discourses, or outrageous actions. The studium inane, or reverie, resembles epilepsy, in which there is no sensibility to the stimuli of external objects. Vigilia, or watchfulness, may be compared to the general writhing of the body; which is just a sufficient exertion to relieve the pain which occafions it. Erotomania may be compared to trismus, or other muscular fixed spasm, without much subsequent pain; and morror to cramp of the muscles of the leg, or other fixed spasm with subsequent pain. All these coincidences contribute to shew, as explained in Sect. III. 5, that our ideas are motions of the immediate organs of fense obeying the same laws as our muscular motions.

The violence of action accompanying infanity depends much on the education of the person; those who have been proudly educated with unrestrained passions, are liable to greater sury; and those, whose education has been humble, to greater despondency. Where the delirious idea, above described, produces pleasurable sensations, as in personal vanity or religious enthusiasm; it is almost a pity to snatch them from their sool's paradise, and reduce them again to the common lot of humanity; lest they should complain of their cure, like the patient described in Horace,

Non fervastis, ait, cui sic extorta voluptas, Et demptus per vim mentis gratissimus error!

As infanities arise from excess of action of the sensorial power of volition, this excess of action may be owing either to the increase of motive or stimulus, or to an increased quantity or accumulation of that sensorial power. And hence, though the greatest number of infanities originate from increased motive to voluntary action, as to avoid pain or to acquire pleasure; yet there appear to be some, which have for their cause an accumu-

lation of the fenforial power of volition.

Thus those, who have been accustomed to perpetual exertions of volition in carrying on some extensive employment or profession during the first half of their lives, are liable to become melancholy, and even to destroy themselves, if they suddenly leave off their very active and anxious exertions, and retire to a situation without employment, of which many instances have occurred. This seems to originate from the pain occasioned by the accumulation of the sensorial power of volition, which now ceases to be expended for want of motive. The tædium vitæ described in No. X. of this genus of diseases affects indolent people, who possess accumulated sensorial power, but want motive to excite it into such actions of the muscles or ideas, as might in part expend it.

The accumulation of fenforial power from the defect of accustomed actions seems to give rise to some inordinate muscular motions, as the incessant jumping of a squirrel confined in a cage, and some of the motions of children confined too long in schools, which are called tricks. See Class III. 1. 1. 1. and IV. 1. 3. 2. And I am inclined to think, that these infanities, which are termed melancholy, where no previous misfortune has occurred, as ingrief or disappointed love, but where the patient sits perpetually brooding over some painful idea, which was not previously excited by any external event, as in the tædium vitæ, are in general occasioned by accumulations of sensorial power; and the violent infanities to increase of motive; that is, to those pains or

want of pleafure, which excite aversion or desire.

There is finally reason to believe, that not only sensorial power in general is capable of accumulation in those parts which have been accustomed to almost perpetual action; but also that each kind or species of sensorial power, as that of irritation, sensation, volition, and association, is separately capable of accumulation in the parts, which have almost perpetually been accumulated by it: which I hope sometime to consider more at large, as I suspect it may supply a key to many of the phænomena not only of infanities and convulsions, but to those of sever.

The disposition to infanity, as well as to convulsion, is believed to be hereditary; and in confequence to be induced in those families from flighter causes than in others. Convulsions have been shewn to have been most frequently induced by pains owing to defect of stimulus, as the shuddering from cold, and not from pains from excess of stimulus, which are generally succeeded by inflammation. But infanities are on the contrary generally induced by pains from excess of stimulus, as from the too violent actions of our ideas, as in common anger, which is an infanity of short duration; for infanities generally, though not always, arife from pains of the organs of fense; but convulsions generally, though not always, from pains of the membranes or glands. And it has been previously explained, that though the membranes and glands, as the stomach and skin, receive great pain from want of stimulus; yet that the organs of fense, as the eye and ear, receive no pain from defect of stimulus.

Hence it follows, that the constitutions most liable to convulsion, are those which most readily become torpid in some part of the system, that is which possess less irritability; and that those most liable to infanity, are such as have excess of sensibility; and lastly, that these two circumstances generally exist in the same constitution; as explained in Sect. XXXI. 2. on Temperaments. These observations explain why epilepsy and infanity frequently succeed or reciprocate with each other, and why inirritable habits, as scrosulous ones, are liable to infanity, of

which I have known fome instances.

In many cases however there is no appearance of the disposition to epilepsy or infanity of the parent being transmitted to the progeny. First, where the infanity has arisen from some violent disappointment, and not from intemperance in the use of spirituous liquors. Secondly, where the parent has acquired the infanity or epilepsy by habits of intoxication after the procreation of his children. Which habits I suppose to be the general cause of the disposition to infanity in this country. See Class III. 1. 7.

As the disposition to gout, dropsy, epilepsy, and infanity, ap-

pears to be produced by the intemperate use of spirituous potation, and is in all of them hereditary; it feems probable, that this disposition gradually increases from generation to generation. in those families which continue for many generations to be intemperate in this respect; till at length these diseases are produced; that is, the irritability of the system gradually is decreased by this powerful stimulus, and the sensibility at the same time increased, as explained in Sect. XXXI. 1. and 2. This disposition is communicated to the progeny, and becomes still increased, if the same stimulus be continued, and so on by a third and fourth generation; which accounts for the appearance of epilepfy in the children of some families, where it was never known before to have existed, and could not be ascribed to their own intemperance. A parity of reasoning shews, that a few sober generations may gradually in the fame manner restore a due degree of irritability to the family, and decrease the excess of sensibility.

From hence it would appear probable, that scrofula and dropfy are diseases from inirritability; but that in epilepsy and insanity an excess of sensibility is added, and the two faulty temper-

aments are thus conjoined.

SPECIES.

1. Mania mutabilis. Mutable madnefs. Where the patients are liable to mistake ideas of sensation for those from irritation, that is, imaginations for realities, if cured of one source of insanity, they are liable in a few months to find another source in some new mistaken or imaginary idea, and to act from this new idea. The idea belongs to delirium, when it is an imaginary or mistaken one; but it is the voluntary actions exerted in consequence of this mistaken idea, which constitute insanity.

In this disease the patient is liable carefully to conceal the object of his desire or aversion. But a constant inordinate sufpicion of all people, and a carelessness of cleanliness, and of decency, are generally concomitants of madness. Their designs cannot be counteracted, till you can investigate the delirious idea or object of their infanity; but as they are generally timid,

they are therefore less to be dreaded.

Z. Z. called a young girl, one of his maid-fervants, into the parlour, and, with cocked piftols in his hands, ordered her to ftrip herfelf naked; he then inspected her with some attention, and dismissed her untouched. Then he stripped two of his male servants in the same manner, to the great terror of the neighbourhood. After he was secured, with much dissiculty he

Vol. II. Q Q wa

was perfuaded to tell me, that he had got the itch, and had examined fome of his fervants to find out from whom he had received it; though at the fame time there was not a fpot to be feen on his hands, or other parts. The outrages in confequence of this false idea were in some measure to be ascribed to the pride occasioned by unrestrained education, assluent wealth, and

dignified family.

Madness is sometimes produced by bodily pain, particularly I believe of a diseased liver, like convulsion and epilepsy; at other times it is caused by very painful ideas occasioned by external circumstances, as of grief, or disappointment; but the most frequent cause of infanity arises from the pain of some imaginary or miftaken idea; which may be termed hallucinatio maniacalis. This hallucination of one of the fenses is often produced in an inftant, and generally becomes gradually weakened in process of time, by the perpetual stimulus of external objects, or by the fuccessions or other catenations of ideas, or by the operations of medicines; and when the maniacal hallucination ceases, or is forgotten, the violent exertions cease, which were in confequence of it, and the disease is cured.

Mr. ——, a clergyman, about forty years of age, who was rather a weak man, happened to be drinking wine in jocular company, and by accident swallowed part of the seal of a letter. which he had just then received; one of his companions seeing him alarmed, cried out in humour, "It will feal your bowels up." He became melancholy from that instant, and in a day or two refused to swallow any kind of nourishment. On being pressed to give a reason for this refusal, he answered he knew nothing would pass through him. A cathartic was given, which produced a great many evacuations, but he still persisted, that nothing passed through him; and though he was frightened into taking a little broth once or twice by threats, yet he foon ceafed intirely to swallow any thing, and died in consequence of this insane idea.

Mits ---, a fenfible and ingenious lady, about thirty, faid she had seen an angel; who told her, that she need not eat, though all others were under the necessity of supporting their earthly existence by food. After fruitless persuasions to take food, the starved herself to death.—It was proposed to send an angel of a higher order to tell her, that now the must begin to

eat and drink again; but it was not put into execution.

Mrs. ____, a lady between forty and fifty years of age, imagined that the heard a voice fay to her one day, as the was at her toilet, "Repent, or you will be damned." From that moment the became melancholy, and this hallucination affected her in greater or less degree for about two years; the then re-

covered perfectly, and is now a cheerful old woman.

Mrs. ____, a farmer's wife, going up stairs to dress, found the curtains of her bed drawn, and on undrawing them, she believed that she saw the corpse of her sister, who was then ill at the distance of twenty miles, and became from that time insane; and as her fifter died about that time, she could not be produced to counteract the infane hallucination, but she perfectly recovered in a few months.

Mrs. _____, a most elegant, beautiful, and accomplished lady, about twenty-two years of age, had been married about two months to an elegant, polished, and affluent young man, and it was well known to be a love-match on both fides. She fuddenly became melancholy, and yet not to fo great a degree, but that she could command herielf to do the honours of her table with grace and apparent ease. After many days intreaty, she at length told me, that she thought her marrying her husband had made him unhappy; and that this idea she could not efface from her mind day or night. I withstood her being confined, as some had advised, and proposed a sea-voyage to her, with expectation that the fickness as well as change of objects, might remove the infane hallucination, by introducing other energetic ideas; this was not complied with, but she travelled about England with her friends and her husband for many months, and at length perfectly recovered, and is now I am informed in health and spirits.

These cases are related to shew the utility of endeavouring to investigate the maniacal idea, or hallucination; as it may not only acquaint us with the probable defigns of the patient, from whence may be deduced the necessity of confinement; but also

may fome time lead to the most effectual plan of cure.

I received good information of the truth of the following cafe, which was published a few years ago in the newspapers. A young farmer in Warwickshire, finding his hedges broke, and the sticks carried away during a frosty season, determined to watch for the thief. He lay many cold hours under a hayflack, and at length an old woman, like a witch in a play, approached, and began to pull up the hedge; he waited till she had tied up her bottle of sticks, and was carrying them off, that he might convict her of the theft, and then ipringing from his concealment, he feized his prey with violent threats. After some altercation, in which her load was left upon the ground, she kneeled upon her bottle of sticks, and raising her arms to Heaven beneath the bright moon then at the full, spoke to the farmer already shivering with cold, "Heaven grant, that thou never mayest

know again the bleffing to be warm." He complained of cold all the next day, and wore an upper coat, and in a few days another, and in a fortnight took to his bed, always faying nothing made him warm, he covered himfelf with very many blankets, and had a fieve over his face, as he lay; and from this one infane idea he kept his bed above twenty years for fear of the cold air, till at length he died.

M. M. As mania arises from pain either of our muscles or organs of sense, the arts of relieving pain must constitute the method of cure. See Sect. XXXIV. 3. 4. Venesection. Vomits of from sive grains to ten of emetic tartar, repeated every third morning for three or four times; with folution of gum ammoniac, and soluble tartar, so as to purge gently every day. Afterwards warm bath for two or three hours a day.

Opium in large doses. Bark. Steel.

Dr. Binns gave two scruples (40 grains) of solid opium at a dose, and twenty grains four hours afterwards; which restored the patient. Dr. Brandreth gave 400 drops of laudanum to a maniac in the greatest possible suror, and in a few hours he became calm and rational. Med. Comment. for 1791, p. 384.

Prognostic.

THE temporary quick pulse attending some maniacal cases is simply a symptom of debility, and is the consequence of too great exertions; but a permanent quick pulse shews the presence of sever, and is frequently a salutary sign; because, if the life of the patient be safe, when the sever ceases, the infanity generally vanishes along with it, as mentioned above. In this case the kind of sever must direct the method of curing the infanity; which must consist of moderate evacuations and diluents, if the pulse be strong; or of nutrientia, bark, and small doses of opium, if the pulse be weak.

Where the cause is of a temporary nature, as in puerperal infanity, there is reason to hope, that the disease will cease, when the bruises, or other painful sensations attending this state, are removed. In these cases the child should be brought frequently to the mother, and applied to her breast, if she will suffer it, and this whether she at first attends to it or not; as by a few trials it frequently excites the storge, or maternal affection,

and removes the infanity, as I have witneffed.

When the madness is occasioned by pain of the teeth, which I believe is no uncommon case, these must be extracted; and the cure follows the extinction of the pain. There is however some difficulty in detecting the delinquent tooth in this case, as

in hemicrania, unless by its apparent decay, or by some previous information of its pain having been complained of; because the pain of the tooth ceases, as soon as the exertions of infanity commence. In this case salivation might be tried.

When a person becomes insane, who has a family of small children to solicit his attention, the prognostic is very unfavourable; as it shews the maniacal hallucination to be more powerful than those ideas which generally interest us the most.

When an infane young man shews no lascivious idea, when an opportunity of gratifying the passion of love is presented to him, as in the case above mentioned of Z. Z. or when an infane young lady shews no symptom of attachment, when addressed honourably by a proper lover, the prognostic is unfavourable, as it shews the maniacal hallucination to affect the mind stronger than the natural passion of love, which in civilized

fociety is strengthened by restraint.

Paralytic affections are faid by Mr. Haslam, to be frequently fucceeded by infanity, and that in these cases the inactivity of some paralytic muscles about the face or limbs with defective memory continue along with the infanity; and he adds that thefe patients are feldom relieved. Observations on Infanity by J. Haslam, 8vo. Rivington. It was before observed, that when fome limbs become paralytic, as in the common hemiplegia, that the other limbs are liable to be for some time in almost perpetual action, owing to the fuperfluity of volition, which was previously expended by the action of those muscles, which are now rendered disobedient to the fenforial power of volition, though they may continue to be excitable by irritation or fenfation, as in the act of pandiculation, or by electric shocks. if this superfluity of voluntary activity be exerted on the organs of fense, delirious hallucinations and infane actions are the confequence; and as the power of life is already injured in a part of the fystem, they are less liable to recover, and die like other paralytic patients. And thus the infanities in confequence of paralytic affections, as well as those in consequence of painful fensations or ideas, countenance the theory, that they arise from the excessive activity of the sensorial power of voli-

2. Studium inane. Reverie confifts of violent voluntary exertions of ideas to relieve pain, with all the trains or tribes connected with them by fenfations or affociations. It frequently afternates with epileptic convulfions; with which it corresponds, in respect to the intensibility of the mind to the stimuli of external objects, in the same manner as madness corresponds with

common

common convultion, in the patient's possessing at the same time a

fensibility of the stimuli of external objects.

Some have been reported to have been involved in reverie for perfectly, as not to have been disturbed by the discharge of a cannon; and others to have been insensible to torture, as the martyrs for religious opinions; but these seem more properly to belong to particular infanities than to reverie, like nostalgia and erotomania.

Reverie is distinguished from madness as described above; and from delirium, because the trains of ideas are kept consistent by the power of volition, as the person reasons and deliberates in it. Somnambulismus is a part of reverie, somnambulism consisting in the exertions of the locomotive muscles, and reverie in the exertions of the organs of sense; See Class I. 1. 9. and Sect. XIX. both which are mixed, or alternate with

each other for the purpose of relieving pain.

When the patients in reverie exert their volition on their organs of fense, they can occasionally perceive the stimuli of external objects, as explained in Sect. XIX. And in this case it resembles sometimes an hallucination of the senses, as there is a mixture of fact and imagination in their discourse; but may be thus distinguished: hallucinations of the senses are allied to delirium, and are attended generally with quick pulse, and other symptoms of great debility; but reverie is without sever, and generally alternates with convulsions; and so much intuitive analogy (see Sect. XVII. 3. 7.) is retained in its paroxysms, as to preserve a consistency in the trains of ideas.

Miss G, whose case is related in Sect. III. 5. 8. said as I once sat by her, "My head is fallen off, see it is rolled to that corner of the room, and the little black dog is nibbling the nose off." On my walking to the place which she looked at, and returning, and affuring her that her nose was unhurt, she became pacified, though I was doubtful whether she attended to

me. See Class III. 1. 1. 9. and Class III. 1. 2. 2.

M. M. Large doses of opium given before the expected par-

oxysm, as in epilepsia dolorifica, Class III. 1. 1. 8.

The hallucinatio studiosa, or false ideas in reverie, differ from maniacal hallucinations above described, as no insane exertions succeed, and in the patients whom I have seen they have always been totally forgotten, when the paroxysm was over.

Master —, a school-boy about twelve years old, after he came out of a convulsion fit and sat up in bed, said to me, "Dont you see my father standing at the seet of the bed, he is come a long way on foot to see me." I answered, no: "What

colour is his coat?" He replied, "A drab colour." "And what buttons?" "Metal ones," he answered, and added, "how fadly his legs are swelled." In a few minutes he said, with apparent surprise, "He is gone," and returned to his perfect mind. Other cases are related in Sect XIX. and XXXIV. 3. and in Class III. 1. 2. 2. with further observations on this kind of hallucination; which however is not the cause of reverie, but constitutes a part of it, the cause being generally some uneasy sensation of the body.

3. Vigilia. Watchfulness confists in the unceasing exercion of volition; which is generally caused by some degree of pain either of mind or of body, or from defect of the usual quantity of pleasurable sensation; hence if those, who are accustomed to wine at night, take tea instead, they cannot sleep. The same happens from want of solid food for supper, to those who are accustomed to use it; as in these cases there is pain or desect of

pleasure in the stomach.

Sometimes the anxiety about fleeping, that is the defire to fleep, prevents fleep; which confifts in an abolition of defire or will. This may fo far be compared to the impediment of speech described in Sect. XVII. 1. 10. as the interference of the will

prevents the effect defired.

Another fource of watchfulness may be from the too great fecretion of sensorial power in the brain, as in phrenzy, and as sometimes happens from the exhibition of opium, and of wine; if the exhaustion of sensorial power by the general actions of the system occasioned by the stimulus of these drugs can be supposed to be less than the increased secretion of it.

M. M. 1. Solid food to supper. Wine. Opium. Warm bath. 2. The patient should be told that his want of sleep is of no consequence to his health. 3. Venesection by cupping. Abstinence from wine. 4. A blifter by stimulating the skin, and rhubarb by stimulating the bowels, will sometimes induce sleep. Exercise. An uniform sound, as of a pausing drop of water, or the murmur of bees. Other means are described in Sect. XVIII. 20.

4. Erotomania. Sentimental love. Described in its excess by romance writers and poets. As the object of love is beauty, and as our perception of beauty consists in a recognition by the sense of vision of those objects, which have before inspired our love, by the pleasure they have afforded to many of our sense (Sect. XVI. 6.); and as brute animals have less accuracy of their sense of vision than mankind (ib.); we see the reason why this kind of love is not frequently observable in the brute creation, except perhaps in some married birds, or in the affection of

the mother to her offspring. Men who have not had leifure to cultivate their taste for visible objects, and who have not read the works of poets and romance-writers, are less liable to sentimental love; and as ladies are educated rather with an idea of being chosen, than of choosing; there are many men and more women, who have not much of this infanity; and are therefore more easily induced to marry for convenience or interest, or from the flattery of one sex to the other.

In its fortunate gratification fentimental love is supposed to supply the purest source of human felicity; and from the suddenness with which many of those patients, described in species I. of this genus, were seized with the maniacal hallucination, there is reason to believe, that the most violent sentimental love may be acquired in a moment of time, as represented by Shakfpeare in the beginning of his Romeo and Juliet, as originally

written.

Some have endeavoured to make a distinction between beauty and grace, and have made them as it were rivals for the possession of the human heart; but grace may be defined beauty in action; for a sleeping beauty cannot be called graceful in whatever attitude she may recline; the muscles must be in action to produce a graceful attitude, and the limbs to produce a graceful motion. But though the object of love is beauty, yet the idea is nevertheless much enhanced by the imagination of the lover; which appears from this curious circumstance, that the lady of his passion feldom appears so beautiful to the lover after a few months separation, as his ideas had painted her in his absence; and there is on that account, always a little disappointment selt for a minute at their next interview from this hallucination of his ideas.

This passion of love produces reverie in its first state, which exertion alleviates the pain of it, and by the assistance of hope converts it into pleasure. Then the lover seeks solitude, lest this agreeable reverie should be interrupted by external stimuli,

as described by Virgil.

Tantum inter denfas, umbrosa cacumina, fagos Assidue veniebat, ibi hæc incondita solus Montibus et sylvis studio jactabat inani.

When the pain of love is fo great, as not to be relieved by the exertions of reverie, as above described; as when it is misplaced on an object, of which the lover cannot possess himself; it may still be counteracted or conquered by the stoic philosophy, which strips all things of their ornaments, and inculcates "nil admirati." Of which lessons may be found in the meditations of Mar-

cus Antoninus. The maniacal idea is faid in some lovers to have been weakened by the action of other very energetic ideas; such as have been occasioned by the death of his favourite child, or by the burning of his house, or by his being shipwrecked. In those cases the violence of the new idea for a while expends so much sensorial power as to prevent the exertion of the maniacal one; and new catenations succeed. On this theory the lover's leap, so celebrated by poets, might effect a cure, if the patient escaped with life.

The third stage of this disease I suppose is irremediable; when a lover has previously been much encouraged, and at length meets with neglect or distain; the maniacal idea is so painful as not to be for a moment relievable by the exertions of reverie, but is instantly followed by surious or melancholy infanity; and suicide, or revenge, have frequently been the consequence. As was lately exemplified in Mr. Hackman, who that Miss Ray in the lobby of the playhouse. So the poet describes the passion

of Dido,

At moriamur, ait,—fic, fic, juvat ire fub umbras!

The story of Medæa seems to have been contrived by Ovid, who was a good judge of the subject, to represent the savage madness occasioned by ill-requited love. Thus the poet,

Earth has no rage like love to hatred turn'd, Nor Hell a fury like a woman fcorn'd.

DRYDEN.

Hence it appears that though fentimental love does not fo frequently arise spontaneously in semale bosoms, yet that it is liable to become as violent, when it has been excited by the courtship of the other sex, and though, when it is rejected, after courtship has produced it, it is not always succeeded by such violent effects as those above mentioned; which may be ascribed to the greater modesty and reserve of their education; yet the disappointed passion is liable to prey upon their minds even to the hazard of their lives, of which I have witnessed two instances, in both which the effects approached to that occasioned by great grief. See Moeror, Class III. 1. 2. 10.

One of these ladies, about 30 years of age, was deserted by an Irish gentleman, who was soon to have married her; she was seized suddenly with a stuper, which by those, who were not acquainted with the cause, was mistaken for a kind of apoplexy; she gradually recovered so as to apply to her usual habits of life,

Vol. II. RR 2

and in four or five years regained her cheerfulness, and married another man. The other was affected with long stupor, loss of digestion, and total inability of mind and body, which continued a year or two, and from which she also gradually recovered.

5. Amor sui. Vanity confifts of an agreeable reverie, and is well ridiculed in the ftory of Narcissus, who so long contemplated his own beautiful image in the water, that he died from neglect of taking sustenance. I once saw a handsome young man, who had been so much flattered by his parents, that his vanity rose so near to infanity, that one might discern by his perpetual attention to himself, and the difficulty with which he arranged his conversation, that the idea of himself intruded itself at every comma or pause of his discourse. In this degree vanity must afford great pleasure to the possession; and when it exists within moderate bounds, may contribute much to the happiness of social life.

My friend Mr. —— once complained to me, that he was much troubled with bathfulness in company, and believed that it arose from his want of personal vanity; on this account he determined on a journey to Paris, when Paris was the centre of politeness; he there learnt to dress, to dance, and to move his hands gracefully in conversation; and returned a most consummate coxcomb. But after a very sew years he relapsed into rus-

ticity of dress and manners.

M. M. The cure of vanity may be attempted by excess of flattery, which will at length appear ridiculous, or by its familiarity will cease to be desired. I remember to have heard a story of a nobleman in the court of France, when France had a court, who was so disagreeably vain in conversation, that the king was pleased to direct his cure, which was shus performed. Two gentlemen were directed always to attend him, one was to stand behind his chair, and the other at a respectful distance before him; whenever his lordship began to speak, one of them always, pronounced "Lord Gallimaustre is going to say the best thing in the world." And, as soon as his Lordship had done speaking, the other attendant pronounced, "Lord Gallimaustre has spoken the best thing in the world." Till in a few weeks this noble lord was so disgusted with praise that he ceased to be vain; and his majesty dismissed his keepers.

6. Noflalgia. Maladie de Pais. Calenture. An unconquerable defire of returning to one's native country, frequent in long voyages, in which the patients become fo infane as to throw themselves into the sea, mistaking it for green fields or meadows. The Swifs are said to be particularly liable to this disease, and

when taken into foreign fervice frequently to defert from this cause, and especially after hearing or singing a particular tune, which was used in their village dances, in their native country, on which account the playing or finging this tune was forbid by the punishment of death. Zwingerus.

> Dear is that shed, to which his foul conforms, And dear that hill, which lifts him to the storms.

7. Spes religiofa. Superstitious hope. This maniacal hallucination in its milder state produces, like sentimental love, an agreeable reverie; but when joined with works of supererogation, it has occasioned many enormities. In India devotees confign themselves by vows to most painful and unceasing tortures, · fuch as holding up their hands, till they cannot retract them; hanging up by hooks put into the thick skin over their shoulders, fitting upon sharp points, and other felf torments. While in our part of the globe falling and mortification, as flagellation, has been believed to please a merciful Deity! The serenity, with which many have suffered cruel martyrdoms, is to be ascribed to

this powerful reverie.

Mr. —, a clergyman, formerly of this neighbourhood, began to bruife and wound himfelf for the fake of religious mortification, and passed much time in prayer, and continued whole nights alone in the church. As he had a wife and family of fmall children, I believed the cafe to be incurable; as otherwife the affection and employment in his family connections would have opposed the beginning of this infanity. He was taken to a madhouse without effect, and after he returned home, continued to beat and bruise himself, and by this kind of mortification, and by fometimes long fasting, he at length became emaciated and died. I once told him in conversation, that "God was a merciful being, and could not delight in cruelty, but that I supposed he worshipped the devil." He was struck with this idea, and promised me not to beat himself for three days, and I believe kept his word for one day. If this idea had been frequently forced on his mind, it might probably have been of

When these works of supererogation have been of a public nature, what cruelties, murders, massacres, has not this infanity introduced into the world !—A commander, who had been very active in leading and encouraging the bloody deeds of St. Bartholomew's day at Paris, on confessing his sins to a worthy ecclesiastic on his death-bed, was asked, "Have you nothing to fay about St Bartholomew?" "On that day," he replied, "God"

Almighty was obliged to me!"-The fear of Hell is another

infanity, which will be spoken of below.

8. Superbia stemmatis. Pride of family has frequently formed a maniacal hallucination, which in its mild state has consisted in agreeable reverie, but when it has been so painful as to demand homage from others, it has frequently induced insane exertions. This infanity seems to have existed in the flourishing state of Rome, as now all over Germany, and is attacked by Juvenal with great severity, a small part of which I shall here give as a method of cure. Sat. 8.

Say, what avails the pedigree, that brings
Thy boasted line from heroes or from kings;
Though many a mighty lord, in parchment roll'd,
Name after name, thy coxcomb hands unfold;
Though wreathed patriots crowd thy marble halls,
Or steel-clad warriors frown along the walls;
While on broad canvas in the gilded frame
All virtues flourish, and all glories stame?—
Say,—if ere noon with idiot laugh you lie
Wallowing in wine, or cog the dubious die,
Or act unshamed, by each indignant buss,
The midnight orgies of promiscuous lust!—
Go, lead mankind to Virtue's holy shrine,

Go, lead mankind to Virtue's holy shrine,
With morals mend them, and with arts refine,
Or lift, with golden characters unsurl'd,
The slag of peace, and save a warring world!—
—So shall with pious hands immortal Fame
Wreathe all her laurels round thy honour'd name,
High o'er thy tomb with chissel bold engrave,
"The Truly Noble are the Good and Brave."

9. Ambitio. Inordinate desire of fame. A carelessness about the opinions of others is said by Xenophon to be the source of impudence; certainly a proper regard for what others think of us frequently incites us to virtuous actions, and deters us from vicious ones; and increases our happiness by enlarging our sphere of sympathy, and by flattering our vanity.

Abstract what others feel, what others think, All pleasures sicken, and all glories sink.

POPE.

When this reverie of ambition excites to conquer nations, or to enflave them, it has been the fource of innumerable wars, and the occasion of a great devastation of mankind. Cæsar is reported to have boasted, that he had destroyed three millions of his enemies, and one million of his friends.

The works of Homer are supposed to have done great injury to mankind by inspiring the love of military glory. Alexander was faid to sleep with them always on his pillow. How like a mad

butcher amid a flock of sheep appears the hero of the Iliad, in the following fine lines of Mr. Pope, which conclude the twentieth book.

His fiery coursers, as the chariot rolls,
Tread down whole ranks, and crush out heroes' souls;
Dash'd from their hoofs, as o'er the dead they fly,
Black bloody drops the smoking chariot dye;

The spiky wheels through heaps of carnage tore,
And thick the groaning axles dropp'd with gore;
High o'er the scene of death Acuillas stood,
All grim with dust, all horrible with blood;
Yet still infatiate, still with rage on slame,
Such is the lust of never dying same!

The cure must be taken from moral writers. Woolaston says, Cæsar conquered Pompey; that is, a man whose name consisted of the letters C, æ, s, a, r, conquered a long time ago a man, whose name consisted of the letters P, o, m, p, e, y, and that this is all that remains of either of them. Juvenal also attacks this mode of infanity, Sat. X. 166.

I, demens, et fævas curre per Alpes, Ut pueris placeas, et declamatio fias!

Which is thus translated by Dr. Johnson,

And left a name, at which the world grew pale, To point a moral, or adorn a tale!

of all the circumstances of some great loss, as of a favourite child. In general the painful ideas gradually decrease in energy, and at length the recollection becomes more tender and less painful. The letter of Sulpicius to Cicero on the loss of his daughter is ingenious. The example of David on the loss of his child is heroic.

A widow lady was left in narrow circumstances with a boy and a girl, two beautiful and lively children, the one fix, and the other seven years of age; as her circumstances allowed her to keep but one maid-servant, these two children were the sole attention, employment, and consolation of her life; she fed them, dressed them, slept with them, and taught them hersels; they were both snatched from her by the gangrenous fore throat in one week: so that she lost at once all that employed her, as well as all that was dear to her. For the first three or four days after their death, when any friend visited her, she fat upright, with her eyes wide open, without shedding tears, and affected to speak of indisferent things. Afterwards she began to weep much, and for some weeks talked to her friends of noth-

ing else but her dear children. But did not for many years, even to her dying hour, get quite over a gloom, which was left

upon her countenance.

In violent grief, when tears flow, it is esteemed a good fymptom; because then the actions caused by sensitive affociation take the place of those caused by volition; that is, they prevent the voluntary exertions of ideas, or mulcular actions, which confti-

tute infanity.

The fobbing and fighing attendant upon grief are not convulfive movements, they are occasioned by the sensorial power being fo expended on the painful ideas, and their connections. that the person neglects to breathe for a time, and then a violent figh or fob is necessary to carry on the blood, which oppresses the pulmonary vessels, which is then performed by deep or quick inspirations, and laborious expirations. Sometimes nevertheless the breath is probably for a while voluntarily held, as an effort to relieve pain. The paleness and ill health occasioned by long grief are spoken of in Class IV. 2. 1. 9.

The melioration of grief by time, and its being at length even attended with pleafure, depends on our retaining a distinct idea of the lost object, and forgetting for a time the idea of the loss of it. This pleasure of grief is beautifully described by Akenfide. Pleasures of Imagination, Book II. 1. 680.

-Ask the faithful youth, Why the cold urn of her, whom long he loved, So often fills his arms; fo often draws His lonely footsteps at the filent hour To pay the mournful tribute of his tears? Oh! he will tell thee, that the wealth of worlds Should ne'er feduce his bosom to forego That facred hour; when, stealing from the noise Of care and envy, fweet remembrance foothes With Virtue's kindest looks his aching breast, And turns his tears to rapture.

M. M. Confolation is best supplied by the Christian doctrine of a happy immortality. In the Pagan religion the power of dying was the great confolation in irremediable distress. Seneca fays, " no one need be unhappy unless by his own fault." And the author of Telemachus begins his work by faying, that Calypso could not console herself for the loss of Ulysses, and found herfelf unhappy in being immortal. In the first hours of grief the method of confolation used by uncle Toby, in Tristram Shandy, is probably the best; "he fat down in an arm chair by the bed of his diffressed friend, and said nothing."

11. Tædium vitæ. Ennui. Irksomeness of life. The inanity of fublunary things has afforded a theme to philosophers, moralitts,

moralists, and divines, from the earliest records of antiquity; "Vanity of vanities!" fays the preacher, "all is vanity!" Solomon. "Man is the dream of a shadow!" Saids wind arthuras. Pindar. O! quantum est in rebus inane! Juvenal. Nor is there any one, I suppose, who has passed the meridian of life, who has not at some moments selt the nihility of all things.

Weariness of life or ennui in its moderate degree has been esteemed a motive to action by some philosophers. See Sect. XXXIV. 2. 3. But in those men, who have run through the usual amusements of life early in respect of their age; and who have not industry or ability to cultivate those sciences, which afford a perpetual fund of novelty, and of consequent entertainment, are liable to become tired of life, as they suppose there is nothing new to be found in it, that can afford them pleasure; like Alexander, who is said to have shed tears because he had not another world to conquer.

Mr. ———, a gentleman, about fifty, of polifhed manners, who in a few months afterwards destroyed himself, said to me one day, "A ride out in the morning, and a warm parlour and a pack of cards in the afternoon, are all that life affords." He was persuaded to have an issue on the top of his head, as he complained of a dull head-ach, which being unskilfully managed, destroyed the pericranium to the size of an inch in diameter; during the time this took in healing, he was indignant about it, and endured life, but soon afterwards shot himself.

Mr.—, a gentleman of Gray's Inn, fome years ago was prevailed upon by his friends to difmifs a mistres, by whom he had a child, but who was so great a termagant and scold, that she was believed to use him very ill, an keven to heat him. He became melancholy in two days from the want of his usual stimulus to action, and cut his throat on the third so completely, that he died immediately.

he died immediately.

Mr. Anson, the brother to the late lord Anson, related to me the following anecdote of the death of lord Sc——. His lord-ship fent to see Mr. Anson on the Monday preceding his death, and faid, "You are the only friend I value in the world, I determined therefore to acquaint you, that I am tired of the insipidity of life, and intend to morrow to leave it." Mr. Anson said, after much conversation, that he was obliged to leave town till Friday, and added, "As you profess a friendship for me, do me this last favour, I entreat you, live till I return." Lerd Sc—— believed this to be a pious artifice to gain time, but nevertheless agreed, if he should return by four o'clock on that day. Mr. Anson did not return till five, and perceived by the countenances of the domestics, that the deed was done. He went

into

into his chamber and found the corpfe of his friend leaning over the arm of a great chair, with the pillol on the ground by him, the ball of which had been discharged into the roof of his mouth,

and passed into his brain.

Mr. - and Mr. -, two young men, heirs to confiderable fortunes, flot themselves at the age of four or five and twenty. without their friends being able to conjecture any cause for those rash actions. One of them I had long known to express himself with diffatisfaction of the world; at eighteen years of age he complained, that he could not entertain himself; he tried to fludy the law at Cambridge, and afterwards went abroad for a year or two by my advice; but returned diffatisfied with all things. As he had an eruption for fome years on a part of his face, which he probably endeavoured to remove by external applications; I was induced to afcribe his perpetual ennui to the pain or disagreeable sensation of a diseased liver. The other young gentleman shot himself in his bed-room, and I was informed that there was found written on a scrap of paper on his table. "I am impotent, and therefore not fit to live." From whence there was reason to conclude, that this was the hallucinatio maniacalis, the delirious idea, which caufed him to destroy himself. The case therefore belongs to mania mutabilis, and not to tædium vitæ.

Those, who have been employed during the first half of their lives in some very active business, and suddenly leave it, are liable to this kind of infanity, and even to suicide; of which I have known two instances, one of them a Birmingham manufacturer, and the other a great and successful commander. This may be ascribed to the accumulation of the sensorial power of volition, and the want of motive to exert or expend it, and which thence becomes painful. See pain of cold from the

want of stimulus. III. 2. 1. 17.

This may afford confolation to those, whose situation in life obliges them to use perpetual industry in their occupations: they may say, that as they have been long in the habit of exerting much voluntary action, they must continue to employ themselves; otherwise that they shall sink into low spirits, as it is called, and become unhappy. And as the continuance of activity is now necessary to their happiness, they had better employ themselves on such objects, as are useful to themselves or their connections, than to consume their time, and misapply their labour, in card-playing, wine-drinking, or fox-hunting, which are other methods of relieving ennui or the irksomeness of life by exertion, and consequent expenditure of voluntary power.

Lefs degrees of this malady are erroneously termed hypochondriacism, driacism, see Class I. 2. 4. 10. by the people, and are generally ascribed to the want of voluntary power, or of industry; but I believe it is generally owing to want of motive or stimulus; and that the pain attending this state of our ideas or muscles is occasioned by accumulation of voluntary power, as above mentioned. The cure of this disease, is popularly known to consist in any kind of voluntary exertion of the mind, or of the body; one of our poets has personissed hypochondriacism, and well advises the use of exercise, or exertion to oppose the monster, and says,

"Throw but a stone, the giant dies."

To this should be added, that those, who have been educated in indolence, do not find or feel ennui, or the pain of existence, when they are inactive; like our domestic animals, as dogs and cats, who sleep by the fire without inclination to hang or drown themselves; as these beings, not having been long accustomed to expend much voluntary power, are not liable to much accus mulation of it, and uneasiness in consequence; which is not so however with the more active squirrel before mentioned.

But on the contrary, those, whose education has induced them to use much voluntary exertion, and have afterwards had no active employment, as happens to some unmarried ladies, are more liable, as I have repeatedly witnessed, to this malady; an

idea, which should be attended to in female education.

Another fource of ennui or tædium vitæ is also derived from wrong education, and is immediately owing to the want of stimulus rather than to the great accumulation of voluntary power; and is liable to attend some ladies in high life, whose exertions during their early years were excited by the flattery of numerous menial servants. And afterwards, when this flattery ceases by their living with their equals, they want their accustomed motive to activity, and in consequence become indolent and unhappy, as surther described in Class III. 2. 1. 8. under the name of Paresis voluntaria.

M. M. The prevention of this malady must consist in the due care of education. Those who are not designed for very active life, particularly young ladies, should not be forced in their early years to use too violent or too constant voluntary exertions. They should not be flattered into all their exertions, but should be taught to act from duty to themselves and others, or for their future advantage as well as for their present amusement.

Some restraint in exhausting the usual pleasures of the world in early life should be laid on young men of fortune; and afterwards the pleasures and solitudes of a matrimonial life are Vol. II. Ss strongly

strongly to be recommended; and finally the cultivation of science, as of chemistry, natural philosophy, natural history, which fupplies an inexhaustible source of pleasurable novelty, and re-

lieves ennui by the exertions it occasions.

In many of these cases, when irksomeness of life has been the oftenfible cause of suicide, there has probably existed a maniacal hallucination, a painful idea, which the patient has concealed even to his dying hour; except where the mania has evidently arisen from hereditary or acquired disease of the membranous or glandular parts of the fystem.

12. Pulchritudinis desiderium. The loss of beauty, either by disease, as by the small-pox, or by age, as life advances, is sometimes painfully felt by ladies, who have been much flattered on account of it. There is a curious case of this kind related in le Sage's Bachelor of Salamanca, which is too nicely defcribed

to be totally imaginary.

In this fituation fome ladies apply to what are termed cofmet ics under various names, which crowd the newspapers. Of these the white has destroyed the health of thousands; a calx, or magistery, of bismuth is supposed to be fold in the shops for this purpose; but it is either, I am informed, in part or entirely white lead or cerussa. The pernicious effects of the external use of those saturnine applications are spoken of in gutta rosea, Class II. 1. 4. 6. The real calx of bismuth would probably have the same ill effect. As the red paint is prepared from cochineal, which is an animal body, less if any injury arises from its use, as it only lies on the skin like other filth.

The tan of the skin occasioned by the sun may be removed by lemon juice evaporated by the fire to half its original quantity, or by diluted marine acid; which cleans the cuticle, by eroding its furface, but requires much caution in the application; the marine acid must be diluted with water, and then put upon the hand or face, after a fecond of time, as foon as the tan disappears, the part must be washed with a wet towel and much warm water. Freckles lie too deep for this operation, nor are they in general removable by a blifter, as I once experienced.

See Class I. 2. 2. 9.

It is probable, that those materials which stain filk, or ivory, might be used to stain the cuticle, or hair, permanently; as they are all animal fubstances. But I do not know, that any trials of this kind have been made on the skin. I endeavoured in vain to whiten the back of my hand by marine acid oxygenated by manganese, which so instantly whitens cotton.

The cure therefore must be fought from moral writers, and

the cultivation of the graces of the mind, which are frequently

a more valuable possession than celebrated beauty.

12. Paupertatis timor. The fear of poverty is one kind of avarice; it is liable to affect people who have left off a profitable and active business; as they are thus deprived of their usual exertions, and are liable to observe the daily expenditure of money, without calculating the fource from whence it flows. It is also liable to occur with a sudden and unexpected increase of fortune. Mr. -, a furgeon, about fifty years of age, who was always rather of a parsimonious disposition, had a large house, with a fortune of forty thousand pounds, left him by a distant relation; and in a few weeks became insane from the fear of poverty, lamenting that he should die in a jail or a workhouse. He had left off a laborious country business, and the daily perception of profit in his books; he also now faw greater expenses going forwards in his new house, than he had been accustomed to observe, and did not so distinctly see the source of fupply; which feems to have occasioned the maniacal hallucination.—This idea of approaching poverty is a very frequent and very painful difease, so as to have induced many to become fuicides, who were in good circumstances; more perhaps than any other maniacal hallucination, except the fear of Hell.

The covetousness of age is more liable to affect single men, than those who have families; though an accumulation of wealth would seem to be more desirable to the latter. But an old man in the former situation, has no personal connections to induce him to open his purse; and having lost the friends of his youth, and not easily acquiring new ones, feels himself alone in the world: feels himself unprotected, as his strength declines, and is thus led to depend for assistance on money, and on that account wishes to accumulate it. Whereas the father of a family has not only those commections, which demand the frequent expenditure of money, but feels a consolation in the friendship of his children, when age may render their good offices necessary

to him.

M. M. I have been well informed of a medical person in good circumstances in London, who always carries an account of his affairs, as debtor and creditor, in his pocket-book; and looks over it frequently in a day, when this disease returns upon him; and thus, by counteracting the maniacal hallucination, wisely prevents the increase of his infanity. Another medical person, in London, is said to have cured himself of this disease by studying mathematics with great attention; which exertion of the mind relieved the pain of the maniacal hallucination.

Many moral writers have stigmatised this infanity; the covet-

ous, they say, commit crimes and mortify themselves without hopes of reward; and thus become miserable both in this world and the next. Thus Juvenal;

Cum furor haud dubius, cum fit manifesta phrenitis, Ut locuples moriaris, egenti vivere fato!

The covetous man thought he gave good advice to the fpendthrift, when he faid, "Live like me," who well answered him,

"That I can do, when all I have is gone!"

POPE.

14. Lethi timor. The fear of death perpetually employs the thoughts of these patients: hence they are devising new medicines, and applying to physicians and quacks without number. It is confounded with hypochondrias, Class I. 2. 3. 9. in popular conversation, but is in reality an infanity.

A young gentleman, whom I advised to go abroad as a cure for this disease, assured me, that during the three years he was in Italy and France he never passed a quarter of an hour without searing he should die. But he has now for above twenty

years experienced the contrary.

The fufferers under this malady are generally at once discoverable by their telling you, amidst an unconnected description of their complaints, that they are nevertheless not afraid of dying. They are also easily led to complain of pains in almost any

part of the body, and are thus foon discovered.

M. M. As the maniacal hallucination has generally arisen in early infancy from some dreadful account of the struggles and pain of dying, I have sometimes observed, that these patients have received great consolation from the instances I have related to them of people dying without pain. Some of these, which I think curious, I shall concisely relate, as a part of the method of cure.

Mr. —, an elderly gentleman, had fent for me one whole day before I could attend him; on my arrival he faid he was glad to fee me, but that he was now quite well, except that he was weak, but had had a pain in his bowels the day before. He then lay in bed with his legs cold up to the knees, his hands and arms cold, and his pulfe fcarcely difcernible, and died in about fix hours. Mr. —, another gentleman about fixty, lay in the act of dying, with difficult refpiration like groaning, but in a kind of stupor or coma vigil, and every ten or twelve minutes, while I fat by him, he waked, looked up, and faid, "who is it

groans

groans so, I am sure there is somebody dying in the room," and then sunk again into a kind of sleep. From these two cases there appeared to be no pain in the act of dying, which may afford consolation to all, but particularly to those who are afflicted with the fear of death.

15. Orci timer. The fear of Hell. Many theatric preachers among the Methodists successfully inspire this terror, and live comfortably upon the folly of their hearers. In this kind of madness the poor patients frequently commit suicide; although they believe they run headlong into the Hell, which they dread! Such is the power of oratory, and such the debility of the hu-

man understanding!

Those, who suffer under this infanity, are generally the most innocent and harmless people; who are then liable to accuse themselves of the greatest imaginary crimes, and have so much intellectual cowardice, that they dare not reason about those things, which they are directed by their priests to believe, however contradictory to human apprehension, or derogatory to the great Creator of all things. The maniacal hallucination at length becomes so painful, that the poor insane slies from life to become free from it.

M. M. Where the intellectual cowardice is great, the voice of reason is ineffectual; but that of ridicule may save many from those mad-making doctors; though it is too weak to cure those, who are already hallucinated. Foote's Farces are recom-

mended for this purpose.

16. Satyriafis. An ungovernable defire of venereal indulgence. The remote cause is probably the stimulus of the semen; whence the phallus becomes distended with blood by the arterial propultion of it being more strongly excited than the correspondent venous absorption. At the same time a new sense is produced in the other termination of the urethra; which, like itching, requires some exterior friction to facilitate the removal of the cause of the maniacal actions, which may probably be increased in those cases by some associated hallucinations of ideas. It differs from priapismus chronicus in the desire of its appropriated object, which is not experienced in the latter, Class I. 1. 4. 6. and from the priapismus amatorius, Class II. 1. 7. 9. in the maniacal actions in consequence of desire. The surrouterinus, or nymphomania, is a similar disease.

M. M. Venefection. Cathartics. Torpentia. Marriage.

17. Ira. Anger is caused by offended pride. We are not angry at breaking a bone, but become quite insane from the smallest streke of a whip from an inserior. Ira suror brevis. Anger is not only itself a temporary madness, but is a frequent at-

tendant

tendant on other infanities, and as, whenever it appears, it diftinguishes infanity from delirium, it is generally a good fign in

fevers with debility.

An injury voluntarily inflicted on us by others excites our exertions of felf-defence or of revenge against the perpetrator of it; but anger does not succeed in any great degree unless our pride is offended; this idea is the maniacal hallucination, the pain of which sometimes produces such violent and general exertions of our muscles and ideas, as to disappoint the revenge we meditate, and vainly to exhaust our sensorial power. Hence angry people, if not surther excited by disagreeable language, are liable in an hour or two to become humble, and forry for their violence, and willing to make greater concessions than required.

M. M. Be filent when you feel yourfelf angry. Never use loud oaths, violent upbraidings, or strong expressions of countenance, or gesticulations of the arms, or clenched fists; as these by their former associations with anger will contribute to increase it. I have been told of a sergeant or corporal, who began moderately to cane his soldiers, when they were awkward in their exercise, but being addicted to swearing and coarse language, he used soon to enrage himself by his own expressions of anger, till toward the end he was liable to beat the delinquents

unmercifully.

18. Rabies. Rage. A defire of biting others, most frequently attendant on canine madness. Animals in great pain, as in the colica faturnina, are said to bite the ground they lie upon, and even their own sless. I have seen patients bite the attendants, and even their own arms, in the epilepsia dolorisica. It seems to be an exertion to relieve pain, as explained in Sect. XXXIV. 1. 3. The dread of water in hydrophobia is occasioned by the repeated painful attempts to swallow it, and is therefore not an essential or original part of the disease called canine madness. See Class III. 1. 1. 15.

There is a mania reported to exist in some parts of the east, in which a man is said to run a muck; and these surious maniacs are believed to have induced their calamity by unlucky gaming, and afterwards by taking large quantities of opium; whence the pain of despair is joined with the energy of drunkenness; they are then said to sally forth into the most populous streets, and to wound and slay all they meet, till they receive their own death, which they desire to procure without the greater guilt,

as they suppose of suicide.

M. M. When there appears a tendency to bite in the painful epilepsy, the end of a rolled up towel, or a wedge of soft wood, should be put into the mouth of the patient. As a bui-

let is faid fometimes to be given to a foldier, who is to be feverely flogged, that he may by biting it better bear his punith-

10. Citta. A defire to swallow indigestible substances. I once faw a young lady, about ten years of age, who filled her stomach with the earth out of a flower-pot, and vomited it up with small stones, bits of wood, and wings of insects amongst it. She had the bombycinous complexion, and looked like a chlorotic patient, though fo young; this generally proceeds from an acid in the ftomach.

M. M. Avomit. Magnefia alba. Armenian bole. Rhu-

barb. Bark. Steel. A blifter. See Class I. 2. 4. 5. 20. Cacositia. Aversion to food. This may arise, without disease of the stomach, from connecting nauseous ideas to our usual food, as by calling a ham a hog's a---. This madness is much inculcated by the stoic philosophy. See Antoninus' See two cases of patients who refused to take nourishment, Class III. 1. 2. 1.

Aversions to peculiar kinds of food are thus formed early in life by affociation of some maniacal hallucination with them, I remember a child, who on tasting the griftle of sturgeon, asked what griftle was? And being told it was like the division of a man's nose, received an ideal hallucination; and for twenty years afterwards could not be perfuaded to tafte sturgeon.

The great fear or aversion, which some people experience at the fight of spiders, toads, crickets, and the like, have generally

had a fimilar origin.

M. M. Affociate agreeable ideas with those which disgust; as call a spider ingenious, a frog clean and innocent; and repress all expressions of disgust by the countenance, as such expressions contribute to preferve, or even to increase the energy of the ideas affociated with them; as mentioned above in Species 17. Ira.

- 21. Syphilis imaginaria. The fear that they are infected with the venereal disease, when they have only deserved it, is a very common infanity amongst modest young men; and is not to be cured without applying artfully to the mind; a little mercury must be given, and hopes of a cure added weekly and gradually by interview or correspondence for fix or eight weeks. Many of these patients have been repeatedly salivated without curing the mind!
- 22. Psora imaginaria. I have twice seen an imaginary itch, and twice an imaginary diabetes, where there was not the least vestige of either of those diseases, and once an imaginary deafness, where the patient heard perfectly well. In all these cases the hallucinated idea is so powerfully excited, that it is not to be

changed

changed suddenly by ocular sensation, or reason. Yet great perseverance in the frequently presenting contrary ideas will fometimes flowly remove this hallucination, or in great length of time oblivion, or forgetfulness, performs a cure, by other

means in vain attempted.

23. Tabes imaginaria. This imaginary difeafe, or hallucina. tion, is caused by the supposed too great frequency of parting with the femen, and had long imposed upon the physician as well as the patient, till Mr. John Hunter first endeavoured to shew, that in general the morbid effects of this pollution were in the imagination; and that those were only liable to those effects in general, who had been terrified by the villanous books. which pretend to prevent or to cure it, but which were purpofely written to vend some quack medicine. Most of those unhappy patients, whom I have feen, had evidently great impression of fear and felf-condemnation on their minds, and might be led to make contradictory complaints in almost any part of the body. and if their confessions could be depended on, had not used this pollution to any great excess.

M. M. 1. Assure them if the loss of the semen happens but twice a week, it will not injure them. 2. Marry them. The last is a certain cure; whether the disease be real or imaginary, Cold partial bath, and aftringent medicines frequently taken, only recal the mind to the disease, or to the delinquency; and thence increase the imaginary effects and the real cause, if such exists. Mr. -- destroyed himself to get free from the pain of fear of the supposed ill consequences of self-pollution, without any other apparent diseate; whose parents I had in vain advised

to marry him, if possible.

24. Sympathia aliena. Pity. Our fympathy with the pleafures and pains of others diftinguishes men from other animals: and is probably the foundation of what is termed our moral sense; and the fource of all our virtues. See Sect. XXII. 3. 3. When our sympathy with those miseries of mankind, which we cannot alleviate, rifes to excess, the mind becomes its own tormentor; and we add to the aggregate fum of human misery, which we ought to labour to diminish; as in the following eloquent lamentation from Akenside's Pleasures of Imagination,

> As midnight florms, the fcene of human things Appear'd before me; deferts, burning fands, Where the parch'd adder dies; the frozen fouth; And defolation blafting all the west With rapine and with murder. Tyrant power Here fits enthroned in blood; the baleful charms

Of supersition there insect the skies,
And turn the sun to horror. Gracious Heaven!
What is the life of man? Or cannot these,
Not these portents thy awful will suffice?
That, propagated thus beyond their scope,
They rise to act their cruelties anew
In my afflicted bosom, thus decreed
The universal sensitive of pain,
The wretched heir of evils not its own!

A poet of antiquity, whose name I do not recollect, is faid to have written a book describing the miseries of the world, and to have destroyed himself at the conclusion of his task. This sympathy, with all fenfitive beings, has been carried fo far by fome individuals, and even by whole tribes, as the Gentoos, as not only to restrain them from killing animals for their support, but even to induce them to permit infects to prey upon their bodies. Such is however the condition of mortality, that the first law of nature is, "Eat or be eaten." We cannot long exist without the destruction of other animal or vegetable beings, either in their mature or their embryon state. Unless the fruits, which furround the feeds of some vegetables, or the honey stolen from them by the bee, may be faid to be an exception to this affertion. See Botanic Garden, P. I. Cant. I. l. 278. Note. Hence, from the necessity of our nature, we may be supposed to have a right to kill those creatures, which we want to eat, or which want to eat us. But to destroy even insects wantonly shews an unreflecting mind or a depraved heart.

Nevertheless mankind may be well divided into the felfish and the social; that is, into those whose pleasures arise from gratifying their appetites, and those whose pleasures arise from their fympathising with others. And according to the prevalence of these opposing propensities we value or dislike the possessor of them.

In conducting the education of young people, it is a nice matter to inspire them with so much benevolent sympathy, or compassion, as may render them good and amiable; and yet not so much as to make them unhappy at the sight of incurable distress. We should endeavour to make them alive to sympathize with all remediable evils, and at the same time to arm them with sortitude to bear the sight of such irremediable evils, as the accidents of life must frequently present before their eyes. About this I have treated more at large in a plan for the conduct of a boarding-school for ladies, which I intend to publish in the course of the next year.

25. Educatio heroica. From the kinds and degrees of infanities already enumerated, the reader will probably recollect ma-

ny more from his own observation; he will perceive that all extraordinary exertions of voluntary action in consequence of some false idea or hallucination, which strongly affects us, may philosophically, though not popularly, be termed an infanity; he will then be liable to divide these voluntary exertions into disagreeable, pernicious, detestable, or into meritorious, delectable, and even amiable, infanities. And will lastly be induced to conceive, that a good education consists in the art of producing such happy hallucinations of ideas, as may be followed by such voluntary exertions, as may be termed meritorious or amiable infanities.

The old man of the mountain in Syria, who governed a fmall nation of people called Affassines, is recorded thus to have educated those of his army who were designed to affassinate the princes with whom he was at war. A young man of natural activity was chosen for the purpose, and thrown into a deep sleep by opium mixed with his food; he was then carried into a garden made to represent the paradise of Mahomet, with flowers of great beauty and fragrance, fruits of delicious slavour, and beautiful Houries beckoning him into the shades. After a while, on being a second time stupissed with opium, the young enthusiast was reconveyed to his apartment; and on the next day was assured by a priest, that he was designed for some great exploit, and that by obeying the commands of their prince, immortal happiness awaited him.

Hence it is easy to collect how the first impressions made on us by accidental circumstances in our infancy continue through life to bias our affections, or mislead our judgments. One of my acquaintance can trace the origin of his own energies of action from some such remote sources, which justifies the observation of M. Rousseau, that the seeds of suture virtues or vices

are oftener fown by the mother than the tutor.

ORDO II.

Decreased Volition.

GENUS I.

With decreased Actions of the Muscles.

Our muscles become fatigued by long contraction, and cease for a time to be excitable by the will; owing to exhaustion of the sensorial power, which resides in them. After a short interval of relaxation the muscle regains its power of voluntary contraction; which is probably occasioned by a new supply of the spirit of animation. In weaker people these contractions cease sooner, and therefore recur more frequently, and are attended with shorter intervals of relaxation, as exemplified in the quickness of the pulse in severe with debility, and in the tremors of

the hands of aged or feeble people.

After a common degree of exhaustion of the sensorial power in a muscle, it becomes again gradually restored by the rest of the muscle, and even accumulated in those muscles, which are most frequently used; as in those which constitute the capillaries of the skin after having been rendered torpid by cold. But in those muscles, which are generally obedient to volition, as those of locomotion, though their usual quantity of sensorial power is restored by their quiescence, or in sleep (for sleep affects these parts of the system only), yet but little accumulation of it succeeds. And this want of accumulation of the sensorial power in these muscles, which are chiefly subservient to volition, explains to us one cause of their greater tendency to paralytic affection.

It must be observed, that those parts of the system, which have been for a time quiescent from want of stimulus, as the vessels of the skin, when exposed to cold, acquire an accumulation of sensorial power during their inactivity; but this does not happen at all, or in much less quantity, from their quiescence after great expenditure of sensorial power by a previous excessive stimulus, as after intoxication. In this case the muscles or organs of sense gradually acquire their natural quantity of sensorial power, as after sleep; but not an accumulation or superabundance of it. And by frequent repetitions of exhaustion by great stimulus, these vessels cease to acquire their whole natural quantity of sensorial power; as in the scirrhous stomach, and scirrhous liver, occasioned by the great and frequent

ftimulus

stimulus of vinous spirit; which may properly be termed irrita-

tive paralysis of those parts of the system.

In the fame manner in common palfies the inaction of the paralytic muscle seems not to be owing to defect of the stimulus of the will, but to exhaustion of sensorial power. Whence it frequently follows great exertion, as in Sect. XXXIV. 1. 7. Thus some parts of the system may cease to obey the will, as in common paralysis; others may cease to be obedient to sensorial in the impotency of age; others to irritation, as in schirrous viscera; and others to association, as in impediment of speech; yet though all these may become inexcitable, or dead, in respect to that kind of stimulus, which has previously exhausted them, whether of volition, or sensorial in respect to the may still in many cases be excited by the others.

SPECIES.

1. Lassimudo. Fatigue or weariness after much voluntary exertion. From the too great expenditure of sensorial power the muscles are with difficulty brought again into voluntary contraction; and seem to require a greater quantity or energy of volition for this purpose. At the same time they still remain obedient to the stimulus of agreeable sensation, as appears in tired dancers finding a renovation of their aptitude to motion on the acquisition of an agreeable partner; or from a tired child riding on a gold-headed cane, as in Sect. XXXIV. 2. 6. These muscles are likewise still obedient to the sensorial power of association, because the motions when thus excited, are performed in their designed directions, and are not broken into variety of gesticulation, as in St. Vitus's dance.

A lassificate likewise frequently occurs with yawning at the beginning of ague-sits; where the production of sensorial power in the brain is less than its expenditure. For in this case the torpor may either originate in the brain, or the torpor of some distant parts of the system may by sympathy affect the brain, though in a less proportionate degree than the parts primarily

affected.

2. Vacillatio senilis. Some elderly people acquire a see-saw motion of their bodies from one side to the other, as they sit, like the oscillation of a pendulum. By these motions the muscles, which preserve the perpendicularity of the body, are alternately quiescent, and exerted; and are thus less liable to fatigue or exhaustion. This therefore resembles the tremors of old people above mentioned, and not those spasmodic movements of the face or limbs, which are called tricks, described in Class IV.

2. 2. which originate from excels of fenforial power, or from efforts to relieve disagreeable sensation, and are afterwards con-

tinued by habit.

3. Tremor senilis. Tremor of old age confilts of a perpetual trembling of the hands, or of the head, or of other muscles, when they are exerted; and is erroneously called paralytic; and feems owing to the fmall quantity of animal power refiding in the muscular fibres. These tremors only exist when the affected muscles are excited into action, as in lifting a glass to the mouth, or in writing, or in keeping the body upright; and cease again, when no voluntary exertion is attempted, as in lying down. Hence these tremors evidently originate from the too quick exhaultion of the lessened quantity of the spirit of animation. So many people tremble from fear or anger, when too great a part of the fenforial power is exerted on the organs of sense, so as to deprive the muscles, which support the body erect, of their due quantity.

4. Brachiorum paralysis. A numbness of the arms is a frequent symptom in hydrops thoracis, as explained in Class I. 2. 3. 14. and in Sect. XXIX. 5. 2.; it also accompanies the asthma dolorificum, Class III. 1. 1. 11. and is owing probably to the fame cause in both. In the colica saturnina a paralysis affects the wrifts, as appears on the patient extending his arm horizontally with the palm downwards, and is often attended with a tumor on the carpal or metacarpal bones. See Class IV. 2. 2. 10.

and I. 2. 4. 8.

Mr. M—, a miner and well-finker, about three years ago, loft the power of contracting both his thumbs; the balls or muscles of the thumbs are much emaciated, and remain paralytic. He ascribes his disease to immersing his hands too long in cold water in the execution of his business. He says his hands had frequently been much benumbed before, so that he could not without difficulty clench them; but that they recovered their motion, as foon as they began to glow, after he had dried and covered them.

In this case there existed two injurious circumstances of different kinds; one the violent and continued action of the muscles, which destroys by exhausting the sensorial power; and the other, the application of cold, which destroys by defect of stimulus. The cold feems to have contributed to the paralyfis by its long application, as well as the continued exertion; but as during the torpor occasioned by the exposure to cold, if the degree of it be not fo great as to extinguish life, the fenforial power becomes accumulated; there is reason to believe, that the exposing a paralytic limb to the cold for a certain time, as by cov-

ering it with fnow or iced water for a few minutes, and then covering it with warm flannel, and this frequently repeated, might, by accumulation of fenforial power, contribute to reftore it to a ftate of voluntary excitability. As this accumulation of fenforial power, and confequent glow, feem, in the prefent cafe, feveral times to have contributed to reftore the numbnefs or inability of those muscles, which at length became paralytic. See Class I. 2. 3. 21.

M. M. Ether externally. Friction. Saline warm bath.

Electricity. Mercurial ointment. See Class I. 2. 4. 8.

5. Raucedo paralytica. Paralytic hoarfeness consists in the almost total loss of voice, which sometimes continues for months, or even years, and is occasioned by inability or paralysis of the recurrent nerves which serve the muscles of vocality, by opening or closing the larynx. The voice generally returns fuddenly, even fo as to alarm the patient. A young lady, who had many months been affected with almost a total loss of voice, and had in vain tried variety of advice, recovered her voice in an instant, on fome alarm as the was dancing at an affembly. Was this owing to a greater exertion of volition than usual? like the dumb young man, the fon of Croefus, who is related to have cried out, when he faw his father's life endangered by the fword of his enemy, and to have continued to speak ever afterwards. Two young ladies in this complaint feemed to be cured by electric thocks passed through the larynx every day for a fortnight. See Raucedo catarrhalis, Class II. 1. 3. 5.

M. M. An emetic. Electric shocks. Mustard-seed, a large spoonful swallowed whole, or a little bruised, every morning. Valerian. Burnt sponge. Blisters on each side of the larynx. Sea-bathing. A gargle of decoction of seneca. Friction. Fre-

quent endeavours to thout and fing.

6. Vesica urinaria paralysis. Paralysis of the bladder is frequently a symptom in irritative fever; in this case the patient makes no water for a day or two; and the tumor of the bladder distended with urine may be seen by the shape of the abdomen, as if girt by a cord below the navel, or distinguished by the hand. Many patients in this situation make no complaint, and suffer great injury by the inattention of their attendants; the water must be drawn off once or twice a day by means of a catheter, and the region of the bladder gently pressed by the hand, whilst the patient is kept in a sitting or erect posture. See Class II. 2. 2. 6.

M. M. Bark. Wine. Opium, a quarter of a grain every fix hours. Balfam of copaiva or of Peru. Tincture of cantharides 20 drops twice a day, or repeated small blifters.

An inability to empty the bladder frequently occurs to elderly men, and is often fatal. This fometimes arises from their having too long been restrained from making water from accidental confinement in public society, or otherwise; whence the bladder has become fo far distended as to become paralytic; and not only this, but the neck of the bladder has become contracted so as to resist the introduction of the catheter. In this deplorable case it has frequently happened, that the forcible efforts to introduce the catheter have perforated the urethra; and the instrument has been supposed to pass into the bladder, when it has only passed into the cellular membrane along the side of it; of which I believe I have seen two or three instances; and afterwards the part has become so much instance as to render the introduction of the catheter into the bladder impracticable.

In this fituation the patients are in imminent danger, and fome have advised a trocar to be introduced into the bladder from the rectum; which I believe is generally followed by an incurable ulcer. One patient, whom I saw in this fituation, began to make a spoonful of water after fix or seven days, and gradually in a few days emptied his bladder to about half its size, and recovered; but I believe he never afterwards was able com-

pletely to evacuate it.

In this fituation I lately advised about two pounds of crude quicksilver to be poured down a glass tube, which was part of a barometer tube, drawn less at one end, and about two feet long, into the urethra, as the patient lay on his back; which I had previously performed upon a horse; this easily passed, as was supposed, into the bladder; on standing erect it did not return, but on kneeling down, and lying horizontally on his hands, the mercury readily returned; and on this account it was believed to have passed into the bladder, as it so easily returned, when the neck of the bladder was lower than the fundus of it. But nevertheless as no urine followed the mercury, though the bladder was violently distended, I was led to believe, that the urethra had been perforated by the previous efforts to introduce a catheter and bougie; and that the mercury had passed on the outside of the bladder into the cellular membrane.

As the urethra is so liable to be perforated by the forcible efforts to introduce the catheter, when the bladder is violently distended in this deplorable disease, I should strongly recommend the injection of a pound or two of crude mercury into the urethra to open by its weight the neck of the bladder previous to any violent or very frequent essays with a catheter whether of metal or of elastic resin.

7. Recli paralysis. Palfy of the rectum. The rectum inter-

tinum, like the urinary bladder in the preceding article, possessed voluntary power of motion; though these volitions are at times uncontrolable by the will, when the acrimony of the contained seces, or their bulk, stimulates it to a greater degree. Hence it happens, that this part is liable to lose its voluntary power by paralysis, but is still liable to be stimulated into action by the contained seces. This frequently occurs in severs, and is a bad sign as a symptom of general debility; and it is the sensibility of the muscular sibres of this and of the urinary bladder remaining, after the voluntarity has ceased, which occasions these two refervoirs so soon to regain, as the sever ceases, their obedience to volition; because the paralysis is thus shewn to be less complete in those cases than in common hemiplegia; as in the latter the sense of touch, though perhaps not the sense of pain, is generally destroyed in the paralytic simb.

M. M. A sponge introduced within the sphincter and to prevent the constant discharge, which should have a string put

through it, by which it may be retracted.

8. Parelis voluntaria. Indolence; or inaptitude to voluntary action. This debility of the exertion of voluntary efforts prevents the accomplishment of all great events in life. It often originates from a mistaken education, in which pleasure or flattery is made the immediate motive of action, and not futue advantage; or what is termed duty. This observation is of great value to those, who attend to the education of their own children. I have feen one or two young married ladies of fortune, who perpetually became uneafy, and believed themselves ill, a week after their arrival in the country, and continued fo uniformly during their stay; yet on their return to London or Bath immediately lost all their complaints, and this repeatedly; which I was led to afcribe to their being in their infancy furrounded with menial attendants, who had flattered them into the exertions they then used. And that in their riper years, they became torpid for want of this stimulus, and could not amuse themselves. by any voluntary employment; but required ever after, either to be amused by other people, or to be flattered into activity. This I suppose, in the other sex, to have supplied one source of ennui and suicide. See Class III. 1. 2. 11.

9. Catalepsis is sometimes used for fixed spalmodic contractions or tetanus, as described in Sect. XXXIV. 1. 5. and in Class III. 1. 13. but is properly simply an inaptitude to muscular motion, the limbs remaining in any attitude in which they are placed. One patient whom I saw in this situation, had taken much mercury, and appeared universally torpid. He sat in a chair in any posture he was put, and held a glass to his mouth

for many minutes without attempting to drink, or withdrawing his hand. He never spoke, and it was at first necessary to compel him to drink broth; he recovered in a few weeks with-

out relapse.

10. Hemiplegia. Palfy of one fide confifts in the total disobedience of the affected muscles to the power of volition. As the voluntary motions are not perpetually exerted, there is little fenforial power accumulated during their quiescence, whence they are less liable to recover from torpor, and are thus more frequently left paralytic, or disobedient to the power of volition, though they are fometimes still alive to painful fensation, as to the prick of a pin, and to heat; also to irritation, as in stretching and yawning; or to electric shocks. Where the paralysis is complete the patient feems gradually to learn to use his limbs over again by repeated efforts, as in infancy; and, as time is required for this purpose, it becomes difficult to know, whether the cure is owing to the effect of medicines, or to the repeated efforts of the voluntary power.

The dispute, whether the nerves decussate or cross each other before they leave the cavities of the skull or spine, seems to be decided in the affirmative by comparative anatomy; as the optic nerves of some fish have been shewn evidently to cross each other; as feen by Haller, Elem. Physiol. t. v. p. 349. Hence the application of blifters or of ether, or of warm fomentations, should be on the fide of the head opposite to that of the affected muscles. This subject should nevertheless be nicely determined, before any one should trepan for the hydrocephalus internus, when the disease is shewn to exist only on one side of the brain, by a fquinting affecting but one eye; as proposed in Clais I. 2. 5. 4. Dr. Sommering has shewn, that a true decusfation of the optic nerves in the human subject actually exists, Elem. of Physiology by Blumenbach, translated by C. Caldwell, Philadelphia. This further appears probable from the oblique direction and infertion of each optic nerve, into the fide of the eye next to the nose, in a direct line from the opposite side of the brain.

The vomiting, which generally attends the attack of hemiplegia, is mentioned in Sect. XX. 8. and is fimilar to that attending vertigo in sea-sickness, and at the commencement of some fevers. Black flools fometimes attend the commencement of hemiplegia, which is probably an effusion of blood from the biliary duct, where the liver is previously affected; or some blood may be derived to the intestines by its escaping from the vena cava into the receptacle of chyle during the diffress of the paralytic attack; and may be conveyed from thence into the intertines by the retrograde motions of the lacteals; as probably fometimes happens in diabetes. See Sect. XXVII. 2. Palfy of one fide of the face is mentioned in Class II. 1. 4. 6. Paralysis of the lacteals, of the liver, and of the veins, which are described in Sect. XXVIII. XXX. and XXVII. do not belong to this class, as they are not diseases of voluntary motions.

M. M. The electric sparks and shocks, if used early in the disease, are frequently of service. A purge of aloes, or calomel. A vomit. Blifter. Saline draughts. Then the bark. Mercurial ointment or fublimate, where the liver is evidently diseased; or where the gutta rosea has previously existed. Sudden alarm. Frequent voluntary efforts. Externally ether. Volatile alkali. Fomentation on the head. Friction. When children, who have fuffered a hemiplegia, begin to use the affeeled arm, the other hand should be tied up for half an hour three or four times a day; which obliges them at their play to use more frequent voluntary efforts with the diseased limb, and thus fooner to reftore the differenced affociations of motion.

In hemiplegia, as well as toward the end of some fevers with great debility, the parts about the loins are liable to mortify by the preflure of a continued recumbency upon them, and in part by the friction of those parts against the sheet, as the patient flides down again after being frequently raifed higher in his bed, to prevent which a pillow should be put beneath the undersheet half way down the bed, as in Class II. 1. 2. 4. A folution of fugar of lead, or white lead in fine powder, or a cerate of lapis calaminaris contributes to heal or to prevent thefe excoriations. But the molt efficacious preventive confifts in the patient's wearing a pair of linen drawers; by which means, when he slides down in his bed, the friction will be between the sheet and his drawers, not between the sheet and his skin; and this greater friction will in general prevent his fliding down in bed, when his head and thoulders are raifed on more pillows, which will on this account also contribute much to his comfort; this is also worthy the attention of those dropsical patients, who are necessitated to lie with the head raised high in bed.

When these patients have any difficulty of swallowing, they should be raised up when any fluid is put into the mouth, lest it thould fuffocate them. See Apoplexia, No. 16. Nor should young children be fed as they lie on their backs, as they are then obliged to fwallow as much as the nurse pleases; like one of the punishments formerly used in the inquisition, where the delinquent was made to swallow many quarts of water, as he was chained down on his back, and was fusfocated by it.

In paralysis of the wrists from lead, Mr. Clutterbuck has late-

ly published some successful cases of the use of mercurial ointment. See Colica Saturnina, I. 2. 4. 8. See Class III. 2. 1. 4.

Dr. J. Alderson has lately much recommended the leaves of rhus toxicodendron (sumach), from i. gr. to iv. of the dried powder to be taken three or four times a day. Effay on Rhus Toxic. Johnson, London, 1793. But it is difficult to know what medicine is of fervice, as the movements of the mulcles mult again be learned, as in infancy, by frequent efforts.

11. Paraplegia. A palfy of the lower half of the body divided horizontally. Animals may be conceived to have double bodies, one half in general refembling fo exactly the other, and being supplied with separate sets of nerves; this gives rise to hemiplegia, or palfy of one half of the body divided vertically; but the paraplegia, or pally of the lower parts of the fystem, depends on an injury of the spinal marrow, or that part of the brain which is contained in the vertebræ of the back; by which all the nerves situated below the injured part are deprived of their nutriment, or precluded from doing their proper offices; and the muscles, to which they are derived, are in confequence disobedient to the power of volition.

This fometimes occurs from an external injury, as a fall from an eminence; of which I faw a deplorable instance, where the bladder and rectum, as well as the lower limbs, were deprived of fo much of their powers of motion, as depended on volition or fensation; but I suppose not of that part of it, which depends on irritation. In the same manner as the voluntary muscles in hemiplegia are fometimes brought into action by irritation, as in stretching or pandiculation, described in Sect. VII. 1. 3.

But the most frequent cause of paraplegia is from a protuberance of one of the spinal vertebræ; which is owing to the innutrition or foftness of bones, described in Class I. 2. 2. 17. The cure of this deplorable difease is frequently effected by the stimulus of an issue placed on each side of the prominent soine, as first published by Mr. Pott. The other means recommended in softness of bones should also be attended to; both in refpect to the internal medicines, and to the mechanical methods of fupporting, or extending the spine; which last, however, in this cale requires particular caution.

12. Somnus. In fleep all voluntary power is suspended, see Sect. XVIII. An unufual quantity of fleep is often produced by weakness. In this case small doses of opium, wine, and bark, may be given with advantage. For the periods of

ileep, see Class IV. 2. 4. 1.

The subsequent ingenious observations on the frequency of

340

the pulse, which fometimes occurs in sleep, are copied from a

letter of Dr. Currie of Liverpool to the author.

"Though rest in general perhaps renders the healthy pulse flower, yet under certain circumstances the contrary is the truth. A full meal without wine or other strong liquor does not increase the frequency of my pulse, while I sit upright, and have my attention engaged. But if I take a recumbent posture after eating, my pulse becomes more frequent, especially if my mind be yacant, and I become drowfy; and, if I flumber, this increased frequency is more considerable with heat and

flushing.

parts affected.

"This I apprehend to be a general truth. The observation may be frequently made upon children; and the restless and feverish nights experienced by many people after a full supper are, I believe, owing to this cause. The supper occasions no inconvenience, whilst the person is upright and awake; but, when he lies down and begins to fleep, especially if he does not perfpire, the fymptoms above mentioned occur. Which may be thus explained in part from your principles. When the power of volition is abolished, the other sensorial actions are increased. In ordinary fleep this does not occasion increased frequency of the pulse; but where sleep takes place during the process of digestion, the digestion itself goes on with increased rapidity. Heat is excited in the system faster than it is expended; and operating on the fenfitive actions, it carries them beyond the limitation of pleasure, producing, as is common in such cases, increased frequency of pulse.

"It is to be observed, that in speaking of the heat generated under these circumstances, I do not allude to any chemical evolution of heat from the food in the process of digestion. I doubt if this takes place to any confiderable degree, for I do not obferve that the parts incumbent on the stomach are increased in heat during the most hurried digestion. It is on some parts of the furface, but more particularly on the extremities of the body, that the increased heat excited by digestion appears, and the heat thus produced arises, as it should seem, from the sympathy between the stomach and the vessels of the skin. The parts most affected are the palms of the hands, and the soles of the feet. Even there the thermometer feldom rifes above 97 or 98 degrees, a temperature not higher than that of the trunk of the body; but three or four degrees higher than the common temperature of these parts, and therefore producing an uneasy senfation of heat, a fenfation increased by the great sensibility of the

"That the increased heat excited by digestion in sleep is the

cause of the accompanying fever, seems to be confirmed by obferving, that if an increased expenditure of heat accompanies the increased generation of it (as when perspiration on the extremities or furface attends this kind of fleep) the frequent pulse and flushed countenance do not occur, as I know by experiment. If, during the feverish sleep already mentioned, I am awakened, and my attention engaged powerfully, my pulse becomes almost immediately slower, and the fever gradually sub-

From these observations of Dr. Currie it appears, that, while in common sleep the actions of the heart, arteries, and capillaries, are strengthened by the accumulation of sensorial power during the fuspension of voluntary action, and the pulse in consequence becomes fuller and flower; in the feverish fleep above described the actions of the heart, arteries, and capillaries, are quickened as well as strengthened by their consent with the increased actions of the stomach, as well as by the stimulus of the new chyle introduced into the circulation. For the stomach, and all other parts of the fystem, being more sensible and more irritable during fleep, Sect. XVIII. 15. and probably more ready to act from affociation, are now exerted with greater velocity as well as strength, constituting a temporary fever of the sensitive irritated kind, refembling the fever excited by wine in the beginning of intoxication; or in some people by a full meal in their waking hours. Sect. XXXV. 1.

On waking, this increased sensibility and irritability of the fystem ceases by the renewed exertions of volition; in the same manner as more violent exertions of volition destroy greater pains; and the pulse in consequence subsides along with the increase of heat; if more violent efforts of volition are exerted, the fystem becomes still less affected by sensation or irritation. Hence the fever and vertigo of intoxication are lessened by intense thinking, Sect. XXI. 8; and insane people are known to bear the pain of cold and hunger better than others, Sect. XXXIV. 2. 5; and lastly, if greater voluntary efforts exist, as in violent anger or violent exercise, the whole system is thrown into more energetic action, and a voluntary fever is induced, as appears by the red skin, quickened pulse, and increase of heat; whence dropfies and fevers with debility are not unfrequently

removed by infanity.

Hence the exertion of the voluntary power in its natural degree diminishes the increased sensibility, and irritability, and probably the increased affociability, which occur during sleep; and thus reduces the frequency of the pulse in the severith sleep after a full meal. In its more powerful state of exertion, it di-

minishes

minishes or destroys sensations and irritations, which are stronger than natural, as in intoxication, or which precede convulsions, or infanity. In its still more powerful degree, the superabundance of this sensorial power actuates and invigorates the whole moving system, giving strength and frequency to the pulse, and an universal glow both of colour and of heat, as in violent and

ger, or outrageous infanities.

If, in the feverish sleep above described, the skin becomes cooled by the evaporation of much perspirable matter, or by the application of cooler air, or thinner clothes, the actions of the cutaneous capillaries are lessened by defect of the stimulus of heat, which counteracts the increase of sensibility during sleep, and the pulsations of the heart and arteries become slower from the lessened stimulus of the particles of blood thus cooled in the cutaneous and pulmonary vessels. Hence the admission of cold air, or ablution with subtepid or with cold water, in severs with hot skin, whether they be attended with arterial strength, or arterial debility, renders the pulse slower; in the former case by diminishing the stimulus of the blood, and in the latter by lessening the expenditure of sensorial power. See Suppl. I. 8. and 15.

13. Incubus. The night-mare is an imperfect fleep, where the defire of locomotion is vehement, but the muscles do not obey the will; it is attended with great uneasiness, a sense of sufficcation, and frequently with sear. It is caused by violent satigue, or drunkenness, or indigestible sood, or lying on the back, or perhaps from many other kinds of uneasiness in our sleep, which may originate either from the body or mind.

Now as the action of respiration is partly voluntary, this complaint may be owing to the irritability of the system being too small to carry on the circulation of the blood through the lungs during sleep, when the voluntary power is suspended. Whence the blood may accumulate in them, and a painful oppression supervene; as in some hamorrhages of the lungs, which occur during sleep; and in patients much debilitated by severs. See

Somnus interruptus, Class I. 2. 1. 3. and I. 2. 1. 9.

Great fatigue with a full fupper and much wine, I have been well informed by one patient, always produced this difease in himself to a great degree. Now the general irritability of the system is much decreased by fatigue, as it exhausts the sensorial power; and secondly, too much wine and stimulating food will again diminish the irritability of some parts of the system, by employing a part of the sensorial power, which is already too small, in digesting a great quantity of aliment; and in increasing the motions of the organs of sense in consequence of some de-

gree of intoxication, whence difficulty of breathing may occur

from the inirritability of the lungs, as in Class I. 2. 1. 3.

This explains an apparent paradox, why people who are feeble, digest their dinners best, if they lie down and sleep, as most animals do, when their stomachs are full. Yet many weak people fleep very uneafily after a large fupper. If the debility of the patient be not very great, and the dinner he has taken, be moderate, the suspension of voluntary action during sleep prevents the expenditure of fo much fenforial power, which may be employed on the actions of the stomach, and thus facilitate the digestive process. If the patient be further exhausted as in the evening, or his debility greater, and fleep enfues after a copious or ttimulating supper, so much sensorial power will be exerted on the actions of the stomach for digestion, that the circulation of the blood through the lungs will be impeded from the diminished irritability to external stimuli, and the absence of volition, as in the incubus, and fomnus interruptus.

M. M. To fleep on a hard bed with the head raifed. Moderate supper. The bark. By sleeping on a harder bed the patient will turn himself more frequently, and not be liable to fleep too profoundly, or lie too long in one posture. To be

awakened frequently by an alarm clock.

14. Lethargus. The lethargy is a flighter apoplexy. It is fuppoted to originate from universal pressure on the brain, and is faid to be produced by compressing the spinal marrow, where there is a deficiency of the bone in the spina bisida. See Sect. XVIII. 20. Whereas in the hydrocephalus there is only a partial pressure of the brain; and probably in nervous fevers with stupor the pressure on the brain may affect only the nerves of the fenses, which lie within the skull, and not those nerves of the medulla oblongata, which principally contribute to move the heart and arteries; whence in the lethargic or apoplectic stupor the pulse is flow as in fleep, whereas in nervous fever the pulse is very quick and feeble, and generally so in hydrocephalus.

In cases of obstructed kidneys, whether owing to the tubuli uriniferi being totally obstructed by calculous matter, or by their paralysis, a kind of drowsiness or lethargy comes on about the eighth or ninth day, and the patient gradually finks. See

Class I. 1. 3. 9.

15. Syncope epileptica, is a temporary apoplexy, the pulse continuing in its natural state, and the voluntary power suspended.

This terminates the paroxysms of epilepsy.

When the animal power is much exhausted by the preceding convulsions, so that the motions from sensation as well as those from volition are suspended; in a quarter or half an hour

the fenforial power becomes restored, and if no pain, or irritation producing pain, recurs, the fit of epilepsy ceases; if the pain recurs, or the irritation, which used to produce it, a new fit of convulsion takes place, and is succeeded again by a syncope. See Epilepsy, Class III. 19-1.7.

16. Apoplexia. Apoplexy may be termed an univerfal palfy, or a permanent fleep. In which, where the pulse is weak, copious bleeding must be injurious; as is well observed by Dr.

Heberden, Trans. of the College.

Mr. —, about 70 years of age, had an apoplectic feizure. His pulse was strong and full. One of the temporal arteries was opened, and about ten ounces of blood suddenly taken from it. He seemed to receive no benefit from this operation; but

gradually funk, and lived but a day or two.

If apoplexy arises from the pressure of blood extravasated on the brain, one moderate venesection may be of service to prevent the further effusion of blood; but copious venesection must be injurious by weakening the patient; since the effused blood must have time, as in common vibices or bruises, to undergo a chemico-animal process, so to change its nature as to sit it for absorption; which may take two or three weeks, which time a patient weakened by repeated venesection or arteriotomy may not survive.

Mrs. —, about 40 years old, had an apoplectic feizure after great exertion from fear; she had lain about 24 hours without speech, or having swallowed any liquid. She was then forcibly raised in bed, and a spoonful of solution of aloes in wine put into her mouth, and the end of the spoon withdrawn, that she might more easily swallow the liquid.—This was done every hour, with broth, and wine and water intervening, till evacuations were procured; which with other means had good effect, and she recovered, except that a considerable degree of hemiple-

gia remained, and some imperfection of her speech.

Many people, who have taken so much vinous spirit as to acquire the temporary apoplexy of intoxication, and are not improperly said to be dead-drunk, have died after copious venesection, I suppose in consequence of it. I once saw at a public meeting two gentlemen in the drunken apoplexy; they were totally insensible with low pulse, on this account they were directed not to lose blood, but to be laid on a bed with their heads high, and to be turned every half hour; as soon as they could swallow, warm tea was given them, which evacuated their stomachs, and they gradually recovered, as people do from less degrees of intoxication.

M. M. Cupping on the occiput. Venefection once in mod-

erate quantity. Warm fomentations long continued and frequently repeated on the shaved head. Solution of aloes. Clysters with solution of aloes and oil of amber. A blister on the spine. An emetic. Afterwards the bark, and small doses of chalybeates. Small electric shocks through the head. Errhines. If small doses of opium? mercurial eintment rubbed on the head or neck?

Where there is a difficulty of fwallowing in apoplectic or paralytic patients, or in those near death in fevers, or other diseases, no fluid should be put into their mouths as they lie upon their backs, lest it should choke them; but they should be raised and supported upright in their beds, and stimulated by strong light, and spoken to in a louder voice, desiring them to swallow, as the sluid is put into the mouth, and the spoon should be immediately withdrawn, that they may close their mouths. Hence if they cannot swallow, it will slow out of their mouths, and not endanger suffocating them. See Hemiplegia, Spec. 10, of this genus.

17. Mors a frigore. Death from cold. The unfortunate travellers, who almost every winter perish in the snow, are much exhausted by their efforts to proceed on their journey, as well as benumbed by cold. And as much greater exercise can be borne without fatigue in cold weather than in warm; because the excessive motions of the cutaneous vessels are thus prevented, and the consequent waste of sensorial power; it may be inferred, that the fatigued traveller becomes paralytic from

violent exertion as well as by the application of cold.

Great degrees of cold affect the motions of those vessels most, which have been generally excited into action by irritation; for when the feet are much benumbed by cold, and painful, and at the same time almost insensible to the touch of external objects, the voluntary muscles retain their motions, and we continue to walk on; the same happens to the singers of children in throwing snow-balls, the voluntary motions of the muscles continue, though those of the cutaneous vessels are benumbed into inactivity.

Mr. Thompson, an elderly gentleman of Shrewsbury, was seized with hemiplegia in the cold bath; which I suppose might be owing to some great energy of exertion, as much as to the coldness of the water. As in the instance given of Mr. Nairn, who, by the exertion to save his relation, perished himself. See

Sect. XXXIV. 1. 7.

Whence I conclude, that, though heat is a fluid necessary to muscular motion, both perhaps by its stimulus, and by its keeping the minute component parts of the ultimate sibrils of the Vol. II.

Www.muscles

muscles or organs of sense at a proper distance from each other; yet paralysis, properly so called, is the consequence of exhaustion of sensorial power by exertion. And that the accumulations of it during the torpor of the cutaneous vessels by exposure to cold, or of some internal viscus in the cold sits of agues, are frequently instrumental in recovering the use of paralytic limbs, or of the motions of other paralytic parts of the system. See

Spec. 4. of this genus.

Animal bodies refift the power of cold probably by their exertions in consequence of the pain of cold, see Botan. Gard. V. 1. additional note xii. But if thefe increased exertions be too violent, fo as to exhauft the fenforial power in producing unnecessary motions, the animal will probably sooner perish. Thus a moderate quantity of wine or spirit repeated at proper intervals of time might be of fervice to those, who are long exposed to excessive cold, both by increasing the action of the capillary vessels, and thus producing heat, and perhaps by increasing in some degree the secretion of sensorial power in the brain. But the contrary must happen when taken immoderately, and not at due intervals. A well-attested history was once related to me of two men, who fet out on foot to travel in the fnow, one of whom drank two or three glasses of brandy before they began ! their journey, the other contented himself with his usual diet and potation; the former of whom perished in spite of any asfistance his companion could afford him; and the other performed his journey with fafety. In this case the sensorial power was exhausted by the unnecessary motions of incipient intoxication by the stimulus of the brandy, as well as by the exertions of walking; which so weakened the dram-drinker, that the cold fooner destroyed him; that is, he had not power to produce sufficient muscular or arterial action, and in consequence sufficient heat, to supply the great expenditure of it. Hence the capillaries of the skin first ceased to act, and became pale and empty; next those which are immediately affociated with them, as the extremities of the pulmonary artery, as happens on going into the cold bath. By the continued inaction of these parts of the vascular system the blood becomes accumulated in the internal arteries, and the brain is supposed to be affected by its compresfion; because these patients are said to sleep, or to become apoplectic, before they die. I overtook a fisherman asleep on his panniers on a very cold frosty night, but on waking him he did not appear to be in any degree of stupor. See Class I. 2. 2. 1.

When travellers are benighted in deep fnow, they might frequently be faved by covering themselves in it, except a small aperture for air; in which situation the lives of hares, sheep,

and other animals, are so often preserved. The snow, both in respect to its component parts, and to the air contained in its pores, is a bad conductor of heat, and will therefore well keep out the external cold; and as the water, when part of it dissolves, is attracted into the pores of the remainder of it, the situation of an animal beneath it is perfectly dry; and, if he is in contact with the earth, he is in a degree of heat between 48, the medium heat of the earth, and 32, the freezing point; that is, in 40 degrees of heat, in which a man thus covered will be as warm as in bed. See Botan. Garden, V. II. notes on Anemone, Barometz, and Muscus. If these facts were more generally understood, it might annually save the lives of many.

After any part of the vascular system of the body has been long exposed to the cold, the sensorial power is so much accumulated in it, that on coming into a warm room the pain of hotach is produced, and inflammation, and consequent mortification, owing to the great exertion of those vessels, when again exposed to a moderate degree of warmth. See Sect. XII. 5. Whence the propriety of applying but very low degrees of heat to limbs benumbed with cold at first, as of snow in its state of dissolving, which is at 32 degrees of heat, or of very cold water. A French writer has observed, that if frozen apples be thawed gradually by covering them with thawing snow, or immersing them in very cold water, they do not lose their taste; if this fact was well ascertained, it might teach us how to preserve other ripe fruits in ice-houses for winter consumption. See Suppl. I.

The pain of cold is probably owing to the accumulation of the fenforial power of irritation. As the skins of those, who have been constantly stimulated into great action by external heat, must soon possess an accumulation of that sensorial power, when the stimulus of heat is withdrawn. See tædium vitæ from accumulation of the sensorial power of volition. III. 1. 2. 11.

manifest and the second

ORDO IL

Decreased Volition.

GENUS H.

With decreased Actions of the Organs of Sense.

SPECIES.

1. Recollectionis jactura. Loss of recollection. This is the defect of memory in old people, who forget the actions of yesterday, being incapable of voluntary recollection, and yet remember those of their youth, which by frequent repetition are introduced by affociation or fuggestion. This is properly the paralysis of the mind; the organs of sense do not obey the voluntary power; that is, our ideas cannot be recollected, or acted over again by the will.

After an apoplectic attack the patients, on beginning to recover, find themselves most at a loss in recollecting proper names of persons or places; as those words have not been so frequently affociated with the ideas they stand for, as the common words of a language. Mr. -, a man of strong mind, of a shortnecked family, many of whom had fuffered by apoplexy, after an apoplectic fit, on his recovering the use of speech, after repeated trials to remember the name of a person or place, applauded himself, when he succeeded, with such a childish smile on the partial return of his fagacity, as very much affected me.-Not long, alas! to return; for another attack in a few weeks destroyed the whole. See Class IV. 2. 3. 8.

I faw a child after the small-pox, which was left in this situation; it was lively, active, and even vigorous; but shewed that kind of furprise, which novelty excites, at every object it viewed; and that as often as it viewed it. I never heard the termin-

ation of the cafe.

2. Stultitia voluntaria. Voluntary folly. The absence of voluntary power and confequent incapacity to compare the ideas of present and future good. Brute animals may be said to be in this fituation, as they are in general excited into action only by their prefent painful or pleafurable fensations. Hence though they are liable to furprise, when their passing trains of ideas are differenced by violent stimuli; yet are they not affected with wonder or altonishment at the novelty of objects; as they posfefs but in a very inferior degree, that voluntary power of com-

paring

paring the present ideas with those previously acquired, which distinguishes mankind; and is termed analogical reasoning, when deliberatively exerted; and intuitive analogy, when used without our attention to it, and which always preserves our hourly trains of ideas consistent with truth and nature. See

Sect. XVII. 3. 7.

3. Ratiocinatio verbofa. Verbal reasoning. This arises from the feeble or inaccurate exertions of the faculty of volition in the act of recalling the ideas of things, and thus mistaking the ideas of words for them. One great imperfection of language confists in the use of what Mr. Horne Tooke calls general terms, as mentioned in Sect. XV. 1. 5. and Sect. XVI. 17. of this work, and which Mr. Locke supposed to express abstracted or general ideas, such as the word castle or army, which in common conversation includes any part or property of those complex things, and is thus liable to mislead inaccurate thinkers. Thus it was said last night, "That horse strikes sire as he passes along the pavement." And it was added jocularly, "that his feet must be as hard as iron," which mistake might arise from the general term, horse, including in common conversation both every part of the animal and his accourtements.

A fecond fource of false reasoning may arise from the same word having two significations totally different from each other; which may mislead those who reason from ideas of words instead of ideas of things. These are generally esteemed witticisms, and are called puns or quibbles; as the jocular syllogism on the word spirit. "Brandy is a spirit; the Devil is a spirit;

therefore brandy is the devil."

A third fource of false reasoning is derived from the two-fold meaning of some sentences, or phrases in all languages; this is also used designedly in jocular compositions, and constitutes the wit of some comedies. An old miller riding on his sack of some saccosted by two young Cantabs, who rode on each side of him, with "Gentlemen of your profession have sometimes a doubtful character—pray, miller, do you think yourself more knave or fool?" the witty miller answered, looking first at one of them and then at the other, "I think myself at present between both." This double entendre of a sentence was used by the priests of the ancient oracles to deceive the inquirer into survey events. As that of

Aio te, Æacide, Romanos vincere posse.

I say, that you, Æacides, the Romans shall conquer.

There is a fourth mode of verbole ratiocination, which confifts in the conclusion of the fyllogism containing an imaginary, but not even a verbal analogy to the preceding propositions. Thus a rustic devotee said to his priest, "I have often wondered, why God Almighty called the first man Adam?" "Don't you know," replied the teacher, "that A is the first letter of the alphabet?" "Aye, so it is," answered the contented inquirer.

Another kind of false reasoning is called by logicians a logical vice; and another kind arises from the first proposition being untrue in respect to its existence: but as all these, and perhaps many other sources of false reasonings, may be resolved into the mittaken use of ideas of words, or general terms, instead of ideas of the things, or parts of things, which they ought to suggest; they belong properly to this article of ratiocinatio verbosa: while the rare faculty of reasoning without words by comparing ideas of things, as in the invention of new machines, and other new discoveries, distinguishes the philosopher from the sophist.

M. M. Children should be permitted to use their hands early in their insancy, and should be supplied with pencils, pens, and various tools; by which they will acquire accurate ideas of external things by the organ of touch, at the same time that they acquire words; and will thence be less liable to be seriously deceived by general terms, or by the double meanings of words, or of sentences, or lastly by salse propositions or inconclusive deductions; and will thus be enabled to compare the analogies of things, and to think without words; the faculty, which constitutes genius, and which so few possess!

4. Credulitas. Credulity. Life is short, opportunities of knowledge rare; our senses are fallacious, our reasonings uncertain, man therefore struggles with perpetual error from the cradle to the cossin. He is necessitated to correct experiment by analogy, and analogy by experiment; and not always to rest satisfied in the belief of facts even with this two-fold testimony, till future opportunities, or the observations of others, concur in

their support.

Ignorance and credulity have ever been companions, and have milled and enflaved mankind; philosophy has in all ages endeavoured to oppose their progress, and to loosen the shackles they had imposed; philosophers have on this account been called unbelievers: unbelievers of what? of the sictions of fancy, of witchcraft, hobgobblins, apparitions, vampires, fairies; of the influence of stars on human actions, miracles wrought by the bones of faints, the slights of ominous birds, the predictions from the bowels of dying animals, expounders of dreams, fortune-tellers, conjurors, modern prophets, necromancy, cheiromancy, animal magnetism, metallic tractors, with endless varie-

ty of folly? These they have disbelieved and despised, but have

ever bowed their hoary heads to Truth and Nature.

Mankind may be divided in respect to the facility of their belief or conviction into two classes; those, who are ready to affent to single facts from the evidence of their senses, or from the ferious affertions of others; and those, who require analogy to corroborate or authenticate them.

Our first knowledge is acquired by our senses; but these are liable to deceive us, and we learn to detect these deceptions by comparing the ideas presented to us by one sense with those presented by another. Thus when we first view a cylinder, it appears to the eye as a flat surface with different shades on it, till we correct this idea by the sense of touch, and find its surface to be circular; that is, having some parts gradually receding further from the eye than others. So when a child, or a cat, or a bird, first sees its own image in a looking-glass, it believes that another animal exists before it, and detects this fallacy by going behind the glass to examine, if another tangible animal really exists there.

Another exuberant fource of error confifts in the falle notions, which we receive in our early years from the defign or ignorance of our inftructors, which affect all our future reasoning by their perpetual intrusions; as those habits of muscular actions of the face or limbs, which are called tricks, when contracted in infan-

cy continue to the end of our lives.

A third great fource of error is the vivacity of our ideas of imagination, which perpetually intrude themselves by various affociations, and compose the farrago of our dreams; in which, by the suspension of volition, we are precluded from comparing the ideas of one sense with those of another, or the incongruity of their successions with the usual course of nature, and thus to detect their fallacy. Which we do in our waking hours by a perpetual voluntary exertion, a process of the mind above mentioned, which we have termed intuitive analogy. Sect. XVII.

This analogy presupposes an acquired knowledge of things, hence children and ignorant people are the most credulous, as not possessing much knowledge of the usual course of nature; and secondly, those are most credulous, whose faculty of comparing ideas, or the voluntary exertion of it, is slow or imperfect. Thus if the power of the magnetic needle of turning towards the north, or the shock given by touching both sides of an electrized coated jar, was related for the first time to a philosopher, and to an ignorant person; the sormer would be less ready to believe them, than the latter; as he would find nothing similar in nature to

compare them to, he would again and again repeat the experiment, before he would give it his entire credence; till by these repetitions it would cease to be a single fact, and would therefore gain the evidence of analogy. But the latter, as having less knowledge of nature, and less facility of voluntary exertion, would more readily believe the affertions of others, or a single fact, as presented to his own observation. Of this kind are the bulk of mankind; they continue throughout their lives in a state of childhood, and have thus been the dupes of priests and poli-

ticians in all countries and in all ages of the world.

In regard to religious matters, there is an intellectual cowardice instilled into the minds of the people from their infancy; which prevents their inquiry: credulity is made an indifpenfable virtue; to inquire or exert their reason in religious matters is denounced as finful; and in the catholic church is punished with more fevere penances than moral crimes. But in respect to our belief of the supposed medical facts, which are published by variety of authors; many of whom are ignorant, and therefore credulous; the golden rule of David Hume may be applied with great advantage. "When two miraculous affertions oppose each other, believe the less miraculous." Thus if a person is faid to have received the small-pox a second time, and to have gone through all the stages of it, one may thus reason: twenty thousand people have been exposed to the variolous contagion a fecond time without receiving the variolous fever, to every one who has been faid to have thus received it; it appears therefore less miraculous, that the affertor of this supposed fact has been deceived, or wishes to deceive, than that it has so happened contrary to the long experienced order of nature.

M. M. The method of cure is to increase our knowledge of the laws of nature, and our habit of comparing whatever ideas are presented to us with those known laws, and thus to counteract the fallacies of our senses, to emancipate ourselves from the false impressions, which we have imbibed in our infancy, and

to fet the faculty of reason above that of imagination.

CLASS IV.

DISEASES OF ASSOCIATION.

ORDO I.

Increased Associate Motions.

GENUS I.

Catenated with Irritative Motions.

THE importance of the subsequent class not only consists in its elucidating all the sympathetic diseases, but in its opening a road to the knowledge of fever. The difficulty and novelty of the subject must plead in excuse for the present impersect state of it. The reader is entreated previously to attend to the following circumstances for the greater facility of investigating their intricate connections; which I shall enumerate under the following heads.

A. Affociate motions distinguished from catenations.

B. Affociate motions of three kinds.

C. Associations affected by external influences.

D. Affociations affected by other fenforial motions.

E. Affociations catenated with fensation.

F. Direct and reverse sympathy.

G. Affociations affected four ways.

H. Origin of affociations.

I. Of the action of vomiting.

K. Tertian affociations.

A. Affociate Motions distinguished from Catenations.

Affociate motions properly mean only those, which are caused by the sensorial power of affociation. Whence it appears, that those sibrous motions, which constitute the introductory link of an affociate train of motions, are excluded from this definition, as not being themselves caused by the sensorial power of affociation, but by irritation, or sensation, or volition. I shall give for example the sushing of the face after dinner; the capillary vestels of the face increase their actions in consequence of their catenation, not their affociation, with those of the stomach; which latter are caused to act with greater energy by the irritation excited by the stimulus of food. These capillaries of the face are affocia-

DISEASES

ted with each other reciprocally, as being all of them excited by the fenforial power of affociation; but they are only catenated with those of the stomach, which are not in this case affociate motions but irritative ones. The common use of the word affociation for almost every kind of connection has rendered this fubject difficult; from which inaccuracy I fear some parts of this work are not exempt.

B. Affociate Motions of three Kinds.

Those trains or tribes of affociate motions, the introductory links of which confifts of an irritative motion, are termed irritative affociations; as when the muscles of the eyelids close the eye in common nictitation. Those, whose introductory link consists of a fensitive motion, are termed fensitive affociations; as when the pectoral and intercostal muscles act in sneezing. And lastly, those whose introductory link consists of a voluntary motion, are termed voluntary affociations; as when the muscles of the lower limbs act in concert with those of the arm in fencing.

C. Affociations affected by external Influences.

Circles of affociate motions, as well as trains and tribes of them, are liable to be affected by external influences, which confift of ethereal fluids, and which, by penetrating the fystem, act upon it perhaps rather as a causa sine qua non of its movements. than directly as a stimulus; except when they are accumulated in unufual quantity. We have a fense adapted to the perception of the excess or defect of one of these fluids; I mean that of elementary heat; in which all things are immerfed. See Class IV. 1 4. 1. But there are others of them, which as we have no power to evade their influence, fo we have no fense to perceive it; these are the solar, and lunar, and terrestrial gravitation, in which also all things are immersed; the electric aura, which pervades us, and is perpetually varying. See Class IV. 1. 4. 5; the magnetic fluid, Class IV. 1. 4. 6; and lastly, the great life-preserver oxygen gas, and the aqueous vapour of the atmosphere, see Class IV. 1. 4. 6. and 7. and 2.

Of these external influences those of heat, and of gravity, have diurnal periods of increase and decrease; besides their greater periods of monthly or annual variation. The manner in which they act by periodical increments on the fystem, till some effect is produced, is spoken of in Sect. XXXII. 3. and 6.

D. Associations affected by other Sensorial Motions.

Circles and trains of affociate motions are also liable to be affected by their catenations with other sensorial powers, as of irritation, or sensation, or volition; which other sensorial powers either thus simply form some of the links of the catenation, or add to the energy of the affociated motions. Thus when vomiting is caused by the stimulus of a stone in the ureter, the sensation of pain seems to be a link of the catenation rather than an efficient cause of the vomiting. But when the capillary vessels of the skin increase their action from the influence of external heat, they are excited both by the stimulus of unusual heat, as well as by the stimulus of the blood, and by their accustomed association with the actions of the heart and arteries. And lastly, in the blush of anger the sensorial power of volition is added to that of association, and irritation, to excite the capillaries of the face with increased action. See Class IV. 2. 3. 5.

E. Affociations catenated with Sensation.

Pain frequently accompanies affociate trains or circles of motion without its being a cause, or a link, of them, but simply an attendant symptom; though it frequently gives name to the disease, as head-ach. Thus in the cramp of the calves of the legs in diarrhæa, the increased sensorial power of affociation is the proximate cause; the preceding increased action of the bowels is the remote cause; and the proximate effect is the violent contractions of the musculi gastrocnemii; but the pain of these muscles is only an attendant symptom, or a remote effect. See Sect. XVIII. 15. Other sensitive affociations are mentioned in Class IV. 1. 2. and IV. 1. 2. 15.

Thus, if the flushing of the face above mentioned after dinner be called a disease, the immediate or proximate cause is the increased power of association, the remote cause is the increased irritative motions of the stomach in consequence of the stimulus of food and wine. The disease or proximate effect consists in the increased actions of the cutaneous vessels of the face; and the sensation of heat, the existence of heat, and the red colour, are attendants or symptoms, or remote effects, of the increased actions of these cutaneous vessels.

F. Direct and reverse Sympathy.

The increased actions of the primary part of the trains of asfociated motions are sometimes succeeded by increased actions Vol. II. of the fecondary part of the train; and fometimes by decreafed actions of it. So likewife the decreafed actions of the primary part of a train of affociate motions are fometimes succeeded by decreased actions of the secondary part, and sometimes by increased actions of it. The former of these situations is called direct fympathy, and the latter reverse fympathy. In general I believe, where the primary part of the train of affociated motions is exerted more than natural, it produces direct sympathy in strong people, and reverse sympathy in weak ones, as a full meal makes fome people hot, and others chill. And where the primary part of the train is exerted less than natural, it produces direct fympathy in weak people, and reverse fympathy in strong ones, as on being exposed for a certain length of time on horseback in a cold day gives indigestion and confequent heart-burn to weak people, and strengthens the digestion, and induces consequent hunger in strong ones. See Sect. XXXV. 1.

This may perhaps be more easily understood, by considering strength and weakness, when applied to animal bodies, as confifting in the quantity of fenforial power refiding in the contracting fibres, and the quantity of stimulus applied, as shewn in Sect. XII. 2. 1. Now when defective stimulus, within certain limits, is partially applied to parts subject to perpetual motion, the expenditure of sensorial power is for a while lessened, but not its general production in the brain, nor its derivation into the weakly stimulated part. Hence in strong people, or such whose fibres abound with sensorial power, if the first tribe of an affociate train of motions be deprived in part of its accustomed stimulus, its action becomes diminished; and the sensorial power becomes accumulated, and by its fuperabundance, or overflowing as it were, increases the action of the second tribe of the affociate actions by reverse sympathy. As exposing the warm skin for a moderate time to cold air increases the action of the stomach, and thus strengthens the power of digestion.

On the reverse, when additional stimulus within certain limits is partially applied to parts, which are descient in respect to the natural quantity of sensorial power, the expenditure of sensorial power is increased, but in a less degree than the increased production of it in the brain, or its increased derivation into the strongly-stimulated organ. Hence in weak people, or such whose sibres are descient of sensorial power, if the first tribe of an associate train of motions be subjected for a while to greater stimulus than usual, a greater production of sensorial power, or a greater derivation of it into the stimulated parts occurs; which by its excess, or overslowing as it were, increases the actions of the second tribe of the associate motions by direct sympathy.

Thus

Thus when vomiting occurs with cold extremities, a blifter on the back in a few hours occasions universal warmth of the skin, and stops the vomiting. And when a diarrhoea occurs with pale skin and cold extremities, the pricking of the points of a stannel shirt, worn next the skin, occasions universal warmth of it, and checks or cures the diarrhoea.

In fome affociate trains of action nevertheless reverse fympathies more frequently occur than direct ones, and in others direct ones more frequently than reverse ones. Thus in continued fever with debility there appears to be a reverse fympathy between the capillary vessels of the stomach and those of the skin; because there exists a total aversion to solid food, and constant heat on the surface of the body. Yet these two systems of vessels are at other times actuated by direct sympathy, as when paleness attends sickness, or cold feet induces indigestion. This subject requires to be further investigated, as it probably depends not only on the present or previous plus or minus of the sensorial power of association, but also on the introduction of other kinds of sensorial power, as in Class IV. 1. 1. D; or the increased production of it in the brain, or the greater mobility of one part of a train of actions than another.

Thus when much food or wine is taken into the stomach, if there be no superfluity of sensorial power in the system, that is, none to be spared from the continual actions of it, a paleness and chillness succeed for a time; because now the expenditure of it by the increased actions of the stomach is greater than the present production of it. In a little time however the stimulus of the food and wine increases the production of sensorial power in the brain, and this produces a superfluity of it in the system; in consequence of which the skin now becomes warm and slorid, which was at first cold and pale; and thus the reverse sympathy is shortly converted into a direct one; which is probably owing to the introduction of a second sensorial power, that

of pleafurable fenfation.

On the contrary, when an emetic drug produces sickness, the skin is at first pale for a time by direct sympathy with the capillaries of the stomach; but in a sew minutes, by the accumulation of sensorial power in the stomach during its less active state in sickness, the capillaries of the skin, which are associated with those of the stomach, act with greater energy by reverse sympathy, and a storid colour returns. Where the quantity of action is diminished in the first part of a train of motions, whether by previous diminution of sensorial power, or present diminution of stimulus, the second part of the train becomes torpid by direct sympathy. And when the quantity of action of the first

part becomes increased by the accumulation of sensorial power during its previous torpor, or by increase of stimulus, the actions of the second part of it likewise become increased by direct sympathy.

In moderate hunger the skin is pale, as before dinner, and in moderate sickness, as no great accumulation of sensorial power has commenced; but in violent hunger, and in greater torpor of the stomach, as from contagious matter, the accumulation of sensorial power becomes so great as to affect the arterial and

capillary system, and fever is produced in both cases.

In contagious fevers with arterial debility commencing with torpor of the stomach, why is the action of the heart weakened, and that of the capillaries increased? Is it because the mobility of the heart is less than that of the stomach, and the mobility of the capillaries greater? Or is it because the association between the muscular fibres of the stomach and those of the heart have been uniformly associated by direct sympathy; and the capillaries of the stomach and those of the skin have been more frequently associated by reverse sympathy?

Where the actions of the stomach have been previously exhausted by long stimulus, as on the day after intoxication, little or no accumulation of sensorial power occurs, during the torpor of the organ, beyond what is required to replace the desiciency of it, and hence sever seldom follows intoxication. And a repetition of the stimulus sometimes becomes necessary even to

induce its natural action, as in dram-drinkers.

Where there has been no previous exhaustion of sensorial power, and the primary link of affociate motions is violently actuated by the sensorial power of sensation, the secondary link is also violently actuated by direct sympathy; as in inslammatory severs. Where however the sensorial power of the system is less than natural, the secondary link of affociated motions becomes torpid by reverse sympathy, as in the inoculated small-pox during the eruption on the sace the seet are frequently cold.

G. Associations affected four Ways.

Hence affociated trains or circles of motions may be affected four different ways. 1. By the greater or less energy of action of the first link with which they are catenated, and from which they take their names; as irritative, sensitive, or voluntary associations. 2. By being excited by two or more sensorial powers at the same time, as by irritation and association, as in the instance of the application of the stimulus of increased external heat to the cutaneous capillaries. 3. By catenation with other

fenforial powers, as with pain or pleasure, which are in this case not the proximate cause of motion, but which, by becoming a link of catenation, excite the sensorial power of association into action; as the pain at the neck of the gall-bladder occasioned by a gall-stone is transferred to the other end of that canal, and becomes a link of catenation between the action of the two extremities of it.

4. The influence of ethereal sluids, as of heat and gravitation. To which last perhaps might be added moisture and oxygen gas as constituting necessary parts of the system, rather than stimuli to excite it into action.

H. The Origin of Associations.

Some trains or circles of affociate motions must have been formed before our nativity, as those of the heart, arteries, and capillaries; others have been affociated, as occasion required them, as the muscles of the diaphragm and abdomen in vomiting; and others by perpetual habit, as those of the stomach with the heart and arteries directly, as in weak pulse during sickness; with the capillaries directly, as in the slushed skin after dinner; and lastly, with the cellular absorbents reversely, as in the increased absorption in anafarca during sickness; and with the irritative motions of the organs of sense reversely, as in vertigo, or sea-sickness. Some of these associations shall be here shortly described to facilitate the investigation of others.

First, other congeries of glands occupy but a particular part of the system, or constitute a particular organ, as the liver, or kidneys; but those glands, which secrete the mucus, and perspirable matter, which are called capillaries, are of very great extent; they receive the blood from the arteries, separate from it the mucus, which lines every cell, and covers every cavity of the body; and the perspirable matter, which softens and lubricates the whole surface of the skin, and the more extensive surface of the air-vessels, which compose the lungs. These are supplied with blood by the perpetual action of the heart and arteries, and have therefore their motions associated with the former, and with each other, by sympathy, which is sometimes di-

rect, and sometimes reverse.

One branch of this affociation, the capillaries of the skin, is very irritable by the increased quantities of cold and heat; another branch, that of the lungs, has not the perception of cold and heat, but is liable by direct sympathy to act in concert with the former, as in going into the cold bath. And it is probable the capillaries of the internal membranes are likewise directly

affected

affected by their fympathy with those of the skin, as appears from the defect of secretion in ulcers during the cold fits of agues.

The motions of this extensive fystem of capillaries, thus affociated by direct fympathy, are also affociated with those of the heart and arteries, sometimes by reverse and sometimes by direct sympathy; and thus constitute simple sever. The cold paroxysm of which consists in their torpor, and the hot one in their orgasm, or increased activity.

I. Of the Action of Vomiting.

The manner, in which the stomach and the diaphragm and abdominal muscles acquire their associate action in vomiting, requires some attention. It is not probable, that this action of vomiting occurs before nativity; as the uniform application of the nutritive liquor amnii to the mouth of the fœtus, and the uniform expenditure of its nourishment, would not feem to give occasion to too great temporary repletion of the stomach; and would preclude the deglutition of any improper material. After nativity the stomach of the child may be occasionally too much diffended with milk; as previous hunger may induce it to overgorge itself; and by repeated efforts the act of vomiting is learned, as a means of getting free from a difagreeable sensation. Thus when any difgustful material, as a bitter drug, is taken into the mouth; certain retrograde motions of the tongue and lips are produced, for the purpose of putting the disagreeable material out of the mouth again.

When the stomach is disagreeably stimulated by the distention or acrimony of the aliment, a similar effort to regurgitate it must occur; and by repeated trials the action of the diaphragm and abdominal muscles by squeezing the stomach assists retrograde exertion to disgorge its contents. In the same manner when a piece of gravel is pushed into the urethra, or a piece of indurated bile into the neck of the gall-bladder, after they have been in vain pressed forward by the usual motions of those ducts, they return into the bladders of gall and urine by the re-

trograde motions of them.

That this is one mode, in which vomiting is induced, appears from the instantaneous rejection from the stomach occasioned by some nauseous drug, or from some nauseous idea; and lastly, from the voluntary power, which some people have been said to have acquired, of emptying their stomachs, much in the same manner as ruminating animals bring up the grass from their first stomach.

There are nevertheless many modes by which these inverted motions

motions of the stomach and cesophagus are induced, and which it is of confequence to diftinguish from each other. The first is the mode above described, where an effort is made to dislodge fomething, which stimulates the stomach into difagreeable senfation; and which is returned by repeated exertions; as when a nauseous drug is taken into the mouth, or a bit of fand falls into the eye, or a drop of water into the wind-pipe. In this the peristaltic motions of the stomach are first stopped, and then reverted by painful fenfation; and the abdominal muscles and diaphragm by repeated efforts become affociated with them. Now as less sensorial power is expended on the retrograde actions of the stomach, and of the lymphatics, which open their mouths on its furface, than by their natural motions, an accumulation of fenforial power in the fibres of the stomach follows the exhibition of an emetic, and on that account an emetic will fometimes stop a spontaneous vomiting which was owing to sensorial deficiency. See Sect. XXXV. 1. 3. and Art. V. 2. 1.

As bitters and metallic falts, exhibited in small doses, stimulate the stomach into greater action, as appears by their increasing the power of digestion, and yet become emetic, when given in larger doses; one might suspect, that they became emetic by inducing debility, and consequent retrograde actions of the stomach, by their previously exhausting the sensorial power by their great stimulus; which might be effected in a moment without producing pain, and in consequence without our perceiving it. But on the contrary, there does notein general appear on the exhibition of emetics to be any previous exhaustion of sensorial power; because there is evidently an accumulation of it during the sickness, as appears from the digestion being stronger afterwards; and from the increased action of the cellular and cutaneous absorbents during its operation. See Art.

Another mode by which vomiting is induced, is owing to debility or deficiency of fensorial power, from the previous exhaustion of it; as on the day after intoxication, or which occurs in people enseebled with the gout, and in dropfy, and in some fevers with debility. In these, when the vomiting ceases, there is no appearance of accumulation of sensorial power, as the digestion still remains weak and impersect.

Another mode by which fickness or vomiting is induced, is by defect of stimulus, as in great hunger; and in those, who have been habituated to spice and spirit with their meals, who are liable to be sick after taking food without these additional stimuli. Other means of inducing sickness by vertigo, or by

nauseous ideas, will be mentioned below.

We shall only add, that the motions of the muscular fibres of the stomach are associated with those of the heart and arteries by direct sympathy, as appears by the weakness of the pulse during the exhibition of an emetic; and that the absorbents of the stomach are associated with the cellular and cutaneous absorbents by reverse sympathy, as is shewn by the great absorption of the mucus of the cells in anasarca during sickness; at the same time that the absorbents of the stomach invert their actions, and pour the mucus and water thus absorbed into that viscus.

In cold paroxysms of sever the stomach partakes of the general torpor, and vomiting is induced by its debility, either by its association with the torpid capillaries, or other torpid parts, or by its own torpor commencing first, and causing the cold fit. The disordered motions of the stomach frequently seem to be the cause or primary seat of sever, as where contagious miasma are swallowed with the saliva, and where sever is produced by sea-sickness, which I once saw. Nevertheless a disorder of the stomach does not always induce sever, as in that case it should constantly attend indigestion, and vertigo, and sea-sickness; but is itself frequently induced by affociation with the disordered movements of other parts of the system, as when it arises from gravel in the ureter, or from a percussion on the head.

The connection of the motions of the stomach with irritative ideas, or motions of the organs of sense, in vertigo, is shewn in Sect. XX. and thus it appears, that many circles of affociation are either directly or reversely affociated, or catenated, with this vicus; which will much contribute to unfold some of the symp-

toms of fever.

K. Tertian Affociations.

The third link of affociate trains of motion is fometimes actuated by reverse sympathy, with the second link, and that by reverse sympathy with the first link; so that the first and third link may act by direct sympathy, and the intermediate one by reverse sympathy. Of this, instances are given in the singultus nephriticus, Class IV. 1. 1. 7. and IV. 2. 1. At other times the tertian or quartan links of affociate motions are actuated by direct sympathy; and that sometimes forwards and sometimes backwards in respect to the usual order of those trains of affociate motions, as in Class IV. 1. 2. 1.

SPECIES.

1. Rubor vultus pransorum. Flushing of the face after dinner

is explained in Sect. XXXV. 1. In the beginning of intoxication the whole skin becomes florid from the association of the actions of the cutaneous arteries with those of the stomach, because vinous spirit excites the sibres of the stomach into more violent action than the stimulus of common food; and the cutaneous capillaries of the face, from their more frequent exposure to the vicissificates of cold and heat, possess more mobility or irritability than those of other parts of the skin, as surther explained in Sect. XXXIII. 2. 10. Vinegar is liable to produce this slussing of the sace, which probably is owing to the quantity of vinous spirit it contains, as I believe the unfermented vegetable acids do not produce this effect. In every kind of blush the arterial blood is propelled into the capillaries safter than the venous absorption can carry it forwards into the veins, in this respect resembling the tensio phalli.

Can the beginning vinous or acetous fermentation of the aliment in weak stomachs contribute to this effect? or is it to be ascribed to the greater power of affociation between the arteries of the face and the sibres of the stomach in some people than in

others?

M. M. Eat and drink less at a time, and more frequently. Put 20 drops of weak acid of vitriol into water to be drunk at meals. Let the dress over the stomach and bowels be loose.

Use no fermented liquors, or vinegar, or spice.

2. Sudor stragulis immersorum. Sweat from being covered in bed. In the commencement of an epidemic fever, in which the perpetual efforts to vomit was a diffressing symptom, Dr. Sydenham discovered, that if the patient's head was for a short time covered over with the bed-clothes, warmth was produced, and a sweat broke out upon the skin, and the tendency to vomit ceased. In this curious fact two trains of affociated motions are excited into increased action. First, the vessels of the lungs are known to have their motion affociated with those of the skin by the difficulty of breathing on going into the cold bath, as described in Sect. XXXII. 3. 2. Hence, when the veffels of the lungs become excited into stronger action, by the bad air under the bed-clothes, warmed and adulterated by frequent breathing, those of the external skin soon become excited by their association into more energetic action, and generate more heat along with a greater fecretion of perspirable matter. Secondly, the fympathy between the stomach and skin is evident in variety of circumstances; thus the cold air of frosty days applied to the skin for a short time increases the action of the stomach by reverse sympathy, but decreases it if continued too long by direct sympathy; so in the circumstance above mentioned, the action VOL. II.

of the stomach is increased by direct sympathy with that of the skin; and the tendency to vomit, which was owing to its diminished action, ceases.

3. Cessatio agritudinis cute excitata. The cure of sickness by stimulating the skin. This is explained in the preceding article; and further noticed in IV. 2. 2. 4. and in IV. 1. 1. F.

Similar to these is the effect of a blister on the back in relieving fickness, indigestion, and heart-burn; and, on the contrary, by these symptoms being frequently induced by coldness of the extremities. The blifter stimulates the cutaneous vessels into greater action; whence warmth and pain are produced at the fame time, and the fibres of the stomach are excited into greater action by their affociation with those of the skin. It does not appear, that the concommitant pain of the blifter causes the increafed energy of the stomach, because the motions of it are not greater than natural; though it is fometimes difficult to determine, whether the primary part of some affociated trains be connected with irritative or fensitive motions.

In the fame manner a flannel shirt, to one who has not been in the habit of wearing one, stimulates the skin by its points, and thus stops vomiting in some cases; and is particularly essicacious in checking fome chronical diarrhœas, which are not attended with fever; for the absorbents of the skin are thus stimulated into greater action, with which those of the intestines confent by direct fympathy.

This effect cannot be ascribed to the warmth alone of the flannel shirt, as being a covering of loose texture, and confining air in its pores, like a fponge, which air is known to be a bad conductor of heat, fince in that case its use should be equally efficacious, if it were worn over a linen shirt; and an increased warmth of the room of the patient would be equally ferviceable.

4. Digestio aucta frigore cutaneo. Digestion increased by coldnels of the skin. Every one has experienced the increase of his appetite after walking in the cool air in frosty days; for there is at this time not only a faving of fenforial power by the less exertion of the cutaneous vessels; but, as these consent with those of the stomach and bowels, this faving of sensorial power is transferred by reverse sympathy from the cutaneous capillaries and abforbents to those of the stomach and intestines.

Hence weak people should use the cold air of winter as a cold bath; that is, they should stay in it but a short time at once, but should immerse themselves in it many times a day.

5. Catarrhus a frigore cutaneo. Catarrh from cold ikin. This has been already explained in Class I. 1. 2. 7. and is further described in Sect. XXXV. 1. 3. In this disease the vessels of the membrane, which lines the nostrils, are excited into greater action; when those of the skin, with which they are associated, are excited into less action by the deficiency of external heat, by reverse sympathy; and though the pain of cold attends the torpor of the primary link of this association, yet the increased motions of the membrane of the nostrils are associated with those of the cutaneous vessels, and not with the pain of them, because no instammation follows.

6. Absorptio cellularis aucta vomitu. In the act of vomiting the irritative motions of the stomach are inverted, and of the absorbents, which open their mouths into it; while the cutaneous, cellular, and pulmonary absorbents are induced, by reverse fympathy with them, to act with greater energy. This is feen in cases of anasarca, when long sickness and vomiting are caused by squills, or antimonial falts, or most of all by the decoction of digitalis purpurea, foxglove; and Mr. J. Hunter mentions a case, in which a large bubo, which was just ready to break, was absorbed in a few days by sickness at sea. Treatise on the Blood, p. 501, which is thus accounted for; lefs fenforial power is expended during fickness by the decreased action of the fibres of the stomach, and of its absorbents; as shewn in Sect. XXXV. 1. 2. whence an accumulation of it is produced, and there is in consequence a greater quantity of sensorial power for the exertion of those motions, which are associated with the absorbents of the stomach by reverse sympathy.

The reverse sympathy between the lacteal and lymphatic branches of the absorbent system have been produced by the one branch being less excited to act, when the other supplies sufficient sluid or nutriment to the sanguiserous vessels. Thus when the stomach is full, and the supply of chyle, and mucus, and water is in sufficient quantity; the pulmonary, cellular, and cutaneous lymphatics are not excited into action; whence the urine is pale, and the skin moist, from the defect of absorption

on those surfaces.

7. Singultus nephriticus. When a stone irritates the ureter, and that even without its being attended with pain or sever, sometimes a chronical hiccough occurs, and continues for days and weeks, instead of sickness or vomiting; which are the common symptoms. In this case the motions of the stomach are decreased by their sympathy with those of the ureter, which are increased by the stimulus of the stone in it; and the increased motions of the diaphragm seem to exist in consequence of their association with the stomach by a second reverse sympathy. This hiccough may nevertheless admit of another explanation, and be supposed to be a convulsive exertion of the diaphragm to re-

PATE

lieve the disagreeable sensation of the stomach in consequence of its disordered irritative associations; and in that case it would belong to Class III. 1. 1. See Class IV. 2. 1. for another example of tertiary association.

M. M. Venefection. Emetic. Calomel. Cathartic, opium, oil of cinnamon, from two to ten drops. Aerated alcaline water.

Peruvian bark.

8. Febris irritativa. Irritative fever, described in Class I. 1. The diseases above explained in this genus are chiefly concerning the sympathies of the absorbent system, or the alimentary canal, which are not fo much affociated with the arterial fystem as to throw it into disorder, when they are slightly deranged; but when any great congeries of conglomerate glands, which may be confidered as the extremities of the arterial syftem, are affected with torpor, the whole arterial system and the heart fympathize with the torpid glands, and act with lefs energy; which constitutes the cold fit of fever; which is therefore at first a decreased action of the associate organ; but as this decrease of action is only a temporary effect, and an increase of exertion both of the torpid glands, and of the whole arterial fystem, soon follows; the hot sit of irritative fever, or fever with strong pulse, properly belongs to this class and genus of diseases.

ORDO I.

Increased Associate Motions.

GENUS II.

Catenated with Sensitive Motions.

THE primary links of the affociated actions of this genus are either produced or attended by painful or pleasurable fensation. The secondary links of the first ten species are attended with increased motions without inflammation, those of the remainder are attended with inflammation. All inflammations, which do not arise in the part which was previously torpid, belong to this genus; as the gout, rheumatism, erysipelas. It is probable many other inflammations may, by future observation, require to be

transplanted into this class.

The circles of fensitive affociate motions consist chiefly of the excretory ducts of the capillaries and of the mouths of the abforbent vessels, which constitute the membranes; and which have been induced into action at the same time; or they consist of the terminations of canals; or of parts which are endued with greater sensibility than those which form the first link of the association. An instance of the first of those is the sympathy between the membranes of the alveolar processes of the jaws, and the membranes above or beneath the muscles about the temples in hemicrania. An instance of the second is in the sympathy between the excretory duct of the lachrymal gland, and the nasal duct of the lachrymal fac. And an instance of the third is the sympathy between the membranes of the liver, and the skin of the face in the gutta rosea of inebriates.

SPECIES.

1. Lachrymarum fluxus sympatheticus. A flow of tears from grief or joy. When the termination of the duct of the lachrymal fac in the nostrils becomes affected either by painful or pleasurable sensations, in consequence of external stimulus, or by its association with agreeable or disagreeable ideas, the motions of the lachrymal gland are at the same time exerted with greater energy, and a prosusion of tears succeeds by sensitive association, as explained in Sect. XVI. 8. 2.

In this case there exists a chain of associated actions, the secretion of the lachrymal gland is increased by whatever stimu-

lates the furface of the eye, at the fame time the increased abundance of tears stimulates the puncta lachrymalia into greater action; and the fluid thus absorbed stimulates the lachrymal fac, and its nasal duct in the nose into greater action. In a contrary direction of this chain of affociation the prefent increase of action is induced. First, the nasal duct of the lachrymal sac is excited into increased action by some pleasurable or painful idea, as described in Sect. XVI. 8. 2. 2d. The puncta lacrymalia or other extremity of the lachrymal fac fympathizes with it (as the two ends of all other canals sympathize with each other.) 2d. With these increased motions of the puncta lacrymalia those of the excretory duct of the lachrymal gland are affociated from their having so perpetually acted together. And, lastly, with the increased actions of the excretory duct of this gland are asfociated those of the other end of it by their frequently acting together; in the same manner as the extremities of other canals are affociated, and thus a greater flow of tears is poured in-

When a flow of tears is produced in grief, it is believed to relieve the violence of it, which is worthy a further inquiry. Painful fenfations, when great, excite the faculty of volition; and the perfon continues voluntarily to call up or perform those ideas, which occasion the painful fensation; that is, the afflicted perfon becomes so far infane or melancholy; but tears are produced by the sensorial faculty of affociation, and shew that the pain is so far relieved as not to excite the excessive power of volition, or infanity, and are therefore a sign of the abatement of the painful state of grief, rather than a cause of that abatement.

See Class III. 1. 2. 10.

2. Sternutatio a lumine. Some perfons fneeze from looking up at the light fky in a morning after coming out of a dark bed room. The olfactory nerves are brought into too great action by their fympathy with the optic nerves, or by their respective fympathies with some intervening parts, as probably with the two extremities of the lachrymal fac; that is, with the puncta lacrymalia and the nafal duct. See Class II. 1. 1. 3.

3. Dolor dentium a stridare. Tooth-edge from grating sounds, and from the touch of certain substances, and even from imagination alone, is described and explained in Sect. XVI. 10. The increased actions of the alveolar vessels or membranes are associated with the ideas, or sensual motions of the auditory nerves in the first case; and of those of the sense of touch, in the second case; and by imagination, or ideas exerted of painful sensation alone, in the last.

Rifus fardonicus. A difagreeable smile attends inslammations

of the diaphragm arising from the affociations of the reiterated exertions of that muscle with those of the lips and cheeks in

laughing. See Diaphragmitis, Class II. 1. 2. 6.

5. Salive fluxus cibo vife. The flow of faliva into the mouths of hungry animals at the fight or smell of food is seen in dogs standing round a dinner-table. The increased actions of the falivary glands have been usually produced by the stimulus of agreeable food on their excretory ducts during the mastication of it; and with this increased action of their excretory ducts the other terminations of those glands in the capillary arteries have been excited into increased action by the mutual affociation of the ends of canals; and at the same time the pleasurable ideas, or sensual motions, of the sense of smell and of sight have accompanied this increased secretion of faliva. Hence this chain of motions becomes affociated with those visual or olfactory ideas, or with the pleasure, which produces or attends them.

6. Tensio mammularum viso puerulo. The nipples of lactescent women are liable to become turgid at the sight of their young offspring. The nipple has generally been rendered turgid by the titillation of the lips or gums of the child in giving suck; the visible idea of the child has thus frequently accompanied this pleasurable sensation of parting with the milk, and turgescence of the tubes, which constitute the nipple. Hence the visual idea of the child, and the pleasure which attends it, become affociated with those increased arterial actions, which swell the cells of the mammula, and extend its tubes; which is very similar to the tensio phalli visa muliere nuda etiam in in-

fomnio.

7. Tensio penis in hydrophobia. An erection of the penis occurs in the hydrophobia, and is a troublefome symptom, as obferved by Cœlius Aurelianus, Fothergill, and Vaughan, and would feem to be produced by an unexplained fympathy between the fenfations about the fauces and the penis. In men the hair grows about both these parts, the voice changes, and the neck thickens at puberty. In the mumps, when the swellings about the throat subside, the testicles are liable to swell. Venereal infection received by the penis is very table to affect the throat with ulcers. Violent coughs, with foreness or rawness about the fauces are often attended with erection of the penis; which is also said to happen to male animals, that are hanged; which last circumstance has generally been ascribed to the obstruction of the circulation of the blood, but is more probably occasioned by the stimulus of the cord in compressing the throat; since if it was owing to impeded circulation it ought equally to occur in drowning animals.

In men the throat becomes so thickened at the time of puberty, that a measure of this is used to ascertain the payment of a poll-tax on males in some of the islands of the Mediterranean, which commences at puberty; a string is wrapped twice round the thinness part of the neck, the ends of it are then put into each corner of the mouth; and if, when thus held in the teeth,

it passes readily over the head, the subject is taxable.

It is difficult to point out by what circumstance the sensitive motions of the penis and of the throat and nose become affociated; I can only observe, that these parts are subjected to greater pleasurable sensations than any other parts of the body; one being designed to preserve ourselves by the pleasure attending the smell and deglutition of food, and the other to ensure the propagation of our species: and may thus gain an affociation of their sensitive motions by their being eminently sensible to pleasure. See Class I. 3. 1. 11. and III. 1. 1. 15. and Sect. XVI.

5. See Gonorrhœa venerea, II. 1. 5. 1.

In the female fex this affociation between the face, throat, nofe, and pubis, does not exist; whence no hair grows on their chins at the time of puberty, nor do their voices change, or their necks thicken. This happens probably from there being in them a more exquisite fenisitve sympathy between the pubis and the breasts. Hence their breasts swell at the time of puberty, and secrete milk at the time of parturition. And in the parotitis, or mumps, the breasts of women swell, when the tumor of the parotitis subsides. See Class I. 1. 2. 15. Whence it would appear, that their breasts possess an intermediate sympathy between the pubis and the throat; as they are the feat of a passion, which men do not possess, that of suckling children.

8. Tenesmus calculosus. The sphincter of the rectum becomes painful or inflamed from the affociation of its sensitive motions with those of the sphincter of the bladder, when the latter is

stimulated into violent pain or inflammation by a stone.

9. Polypus narium ex afcaridibus? The stimulation of ascarides in the rectum produces, by sensitive sympathy, an itching of the nose, as explained in IV. 2. 2. 6; and in three children I have seen a polypus in the nose, who were all affected with ascarides; to the perpetual stimulation of which, and the consequent sensitive association, I was led to ascribe the inflammation and thickening of the membrane of the nostrils.

10. Crampus furarum in cholera. A cramp of the muscles of the legs occurs in violent diarrhoea, or cholera, and from the use of too much acid diet in gouty habits. This teems to sympathize with uneasy sensation in the bowels. See Class III. 1.

1. 14. This association is not easily accounted for, but is anal-

ogous in some degree to the paralysis of the muscles of the arms in colica faturnina. It would feem, that the muscles of the legs in walking get a sympathy with the lower parts of the intestines. and those of the arms in variety of employment obtain a sympathy with the higher parts of them. See Cholera and Ileus.

11. Zona ignea nephritica. Nephritic shingles. The external skin about the loins and sides of the belly I suppose to have greater mobility in respect to sensitive association, than the external membrane of the kidney; and that their motions are by fome unknown means thus affociated. When the torpor or beginning inflammation of this membrane ceases, the external skin becomes inflamed in its stead, and a kind of herpes, called the fhingles, covers the loins and fides of the belly. See Class II.

12. Eruptio variolarum. After the inflammation of the inoculated arm has spread for a quarter of a lunation, it affects the stomach by reverse sympathy; that is, the actions of the stomach are affociated with those of the skin; and as much sensorial power is now exerted on the inflamed skin, the other part of this fensitive affociation is deprived of its natural share, and becomes torpid, or inverts its motions. After this torpor of the ftomach has continued a time, and much fenforial power is thus accumulated; other parts of the skin, which are also associated. with it, as that of the face first, are thrown into partial inflammation; that is the eruptions of the small-pox appear on the face.

For that the variolus matter affects the stomach previous to its eruption on the skin, appears from the sickness at the commencement of the fever; and because, when the morbid motions affect the skin, those of the stomach cease; as in the gout and erysipelas, mentioned below. The consent between the stomach and the skin appears in variety of other diseases; and as they both confift of furfaces, which absorb and secrete a quantity of moisture, their motions must frequently be produced together, or in succession; which is the foundation of all the sympathies of animal motions, whether of the irritative, fensitive, or voluntary kinds.

Now as the skin, which covers the face, is exposed to greater variations of heat and cold than any other part of the body; it probably possesses more mobility to sensitive associations, not only than the stomach, but than any other part of the skin; and is thence affected at the eruption of the small-pox with violent action and consequent inflammation, by the affociation of its motions with those of the stomach, a day before the other parts of

Vol. H. A Sail word A A a"

the skin; and becomes fuller of pustules, than any other part of

the body. See Class II. 1. 3. 9.

It might be supposed, that the successive swelling of the hands. when the face subsides, at the height of the small-pox, and of the feet, when the hands fubfide, were governed by some unknown affociations of those parts of the system; but these successions of tumor and subsidence more evidently depend on the times of the eruption of the pultules on those parts, as they appear a day fooner on the face than on the hands, and a day fooner on the hands than on the feet, owing to the greater comparative mobility of those parts of the skin.

13. Gutta rosea stomatica. Stomatic red face. On drinking cold water, or cold milk, when heated with exercise, or on eating cold vegetables, as raw turnips, many people in harvest-time have been afflicted with what has been called a furfeit. The stomach becomes painful, with indigestion and statulency, and after a few days an eruption of the face appears, and continues with fome relief, but not with entire relief; as both the pimpled face and indigestion are liable to continue even to old age.

M. M. Venesection. A cathartic with calomel. Then half a grain of opium twice a day for many weeks. If faturated folution of arfenic three or five drops twice or thrice a day for a

week?

14. Gutta rosea hepatica. The rosy drop of the face of some drinking people is produced like the gout described below, in confequence of an inflamed liver. In these constitutions the skin of the face being exposed to greater variation of heat and cold than the membranes of the liver, possesses more mobility than those hepatic membranes; and hence by whatever means these membranes are induced to sympathize, when this sensitive affociation occurs, the cutaneous veffels of the face run into greater degrees of those motions, which constitute inflammation, than previously existed in the membranes of the liver; and then those motions of the liver cease. See Class II. 1. 4. 6.

As inflammation of the liver fo frequently attends the great potation of vinous spirit, there is reason to suspect, that this viscus itself becomes inflamed by fensitive affociation with the stomach; or that, when one termination of the bile-duct, which enters the duodenum, is stimulated violently, the other end may

become inflamed by fensitive affociation.

15. Podagra. The gout, except when it affects the liver or stomach, seems always to be a secondary disease, and, like the rheumatism and erysipelas mentioned below, begins with the torpor of some distant part of the system.

The most frequent primary feat of the gout I suppose to be

the liver, which is probably affected with torpor not only previous to the annual paroxysms of the gout, but to every change of its fituation from one limb to another. The reasons, which induce me to suspect the liver to be first affected, are not only because the jaundice sometimes attends the commencement of gout, as described in Sect. XXIV. 2. 8. but a pain also over the pit of the stomach, which I suppose to be of the termination of the bile-duct in the duodenum, and which is erroneously supposed to be the gout of the stomach, with indigestion and flatulency, generally attends the commencement of the inflammation of each limb. See Arthritis ventriculi, Class I. 2. 4. 6. In the two cases, which I saw, of the gout in the limbs being preceded by jaundice, there was a cold shivering fit attended the inflammation of the foot, and a pain at the pit of the stomach; which ceased along with the jaundice, as soon as the foot became inflamed. This led me to suspect, that there was a torpor of the liver, and perhaps of the foot also, but nevertheless the liver might also in this case be previously inflamed, as observed in Sect. XXIV. 2. 8.

Now as the membranes of the joints of the feet fuffer greater variations of heat and cold than the membranes of the liver, and are more habituated to extension and contraction than other parts of the skin in their vicinity; I suppose them to be more mobile, that is, more liable to run into extremes of exertion or quiescence; and are thence more susceptible of inflammation, than fuch parts as are less exposed to great variations of heat

and cold, or of extension and contraction.

When a stone presses into the sphincter of the bladder, the glans penis is affected with greater pain by fympathy, owing to its greater fensibility, than the sphincter of the bladder; and when this pain commences, that of the iphincter ceases, when the stone is not too large, or pushed too far into the urethra. Thus when the membrane, which covers the ball of the great toe, fympathizes with some membranous part of a torpid or inflamed liver; this membrane of the toe falls into that kind of action, whether of torpor or inflammation, with greater energy, than those actions excited in the diseased liver; and when this new torpor or inflammation commences, that with which it fympathizes ceases; which I believe to be a general law of affociated inflammations.

The paroxysms of the gout would seem to be catenated with folar influence, both in respect to their larger annual periods, and to their diurnal periods-See Sect. XXXVI. 3. 6.-as the former occur about the same season of the year, and the latter commence about an hour before fun-rife; nevertheless the annual periods may depend on the fuccession of great vicissitudes of cold and heat, and the diurnal ones on our increased fensibility to internal fensations during sleep, as in the fits of asthma,

and of some epilepsies. See Sect. XVIII. 15.

In respect to the pre-remote cause or disposition to the gout. there can be no doubt of its individually arifing from the potation of fermented or spirituous liquors in this country; whether opium produces the same effect in the countries, where it is in daily use, I have never been well informed. See Sect. XXI. 10. where this subject is treated of; to which I have to add, that I have feen some, and heard of others, who have moderated their paroxysms of gout, by diminishing the quantity of fermented liquors, which they had been accustomed to; and others who, by a total abitinence from fermented liquors, have entirely freed themselves from this excruciating malady; which otherwise grows with our years, and curtails or renders miserable the latter half, or third, of the lives of those, who are subject to it. The remote cause is whatever induces temporary torpor or weakness of the system; and the proximate cause is the inirritability, or defective irritation, of some part of the system; whence torpor and confequent inflammation. The great Sydenham faw the beneficial effects of the abstinence from fermented liquors in preventing the gout, and adds, "if an empiric " could give small-beer only to gouty patients as a nostrum, and " perfuade them not to drink any other spirituous fluids, he " might rescue thousands from this disease, and acquire a for-"tune for his ingenuity." Yet it is to be lamented, that this accurate observer of diseases had not resolution to practise his own prescription, and thus to have set an example to the world of the truth of his doctrine; but, on the contrary, recommended Madeira, the strongest wine in common use, to be taken in the fits of the gout, to the detriment of thousands; and is said himfelf to have perithed a martyr to the difease, which he knew how to fubdue!

As example has more forcible effect than simple affertion, I shall now concilely relate my own case, and that of one of my most respected friends. E. D. was about forty years of age, when he was first seized with a fit of the gout. The ball of his right great toe was very painful, and much swelled and inflamed, which continued five or fix days in spite of venesection, a a brisk cathartic with ten grains of calomel, and the application of cold air and cold water to his foot. He then ceased to drink ale or wine alone; confining himfelf to small-beer, or wine diluted with about thrice its quantity of water. In about a year he fuffered two other fits of the gout, in less violent degree. He

then totally abstained from all fermented liquors, not even tasting small-beer, or a drop of any kind of wine; but ate plentifully of slesh-meat, and all kinds of vegetables, and fruit, using for his drink at meals chiefly water alone, or lemonade, or cream

water; with tea and coffee between them as usual.

By this abstinence from fermented liquors he kept quite free from the gout for fifteen or fixteen years; and then began to take small-beer mixed with water occasionally, or wine and water, or perry and water, or cyder and water; by which indulgence after a few months he had again a paroxysm of gout, which continued about three days in the ball of his toe; which occasioned him to return to his habit of drinking water, and he has now for above twenty years kept in perpetual health, except accidental colds from the changes of the seasons. Before he abstained from fermented or spirituous liquors, he was frequently subject to the piles, and to the gravel, neither of which he has since experienced.

In the following case the gout was established by longer habit and greater violence, and therefore required more cautious treatment. The Rev. R. W. was feized with the gout about the age of thirty-two, which increased so rapidly that at the age of forty-one he was confined to his room seven months in that year: he had fome degree of lameness during the intervals, with chalky fwellings of his heels and elbows. As the difease had continued fo long and fo violently, and the powers of his digeftion were somewhat weakened, he was advised not entirely to leave off all fermented liquors; and as small-beer is of such various strength, he was advised to drink exactly two wine-glasses, about four ounces, of wine mixed with three or four times its quantity of water, with or without lemon and fugar, for his daily potation at dinner, and no other fermented liquor of any kind; and was advised to eat flesh-meat with any kind of boiled vegetables, and fruit, with or without spice. He has now scrupulously continued this regimen for above five years, and has had an annual moderate gouty paroxylm of a few weeks. instead of the confinement of so many months, with great health and good spirits during the intervals.

The following is a more particular account of the history of this case; being part of a letter which Mr. Wilmot wrote on

that fubject at my entreaty.

"I entered into the army with an excellent constitution at the age of fisteen. The corps I served in was distinguished by its regularity, that is, the regular allowance of the meis was only one pint of wine per man each day; unless we had company to dine with us; then, as was the general custom of the time, the bottle circulated without limit. This mode of living, though by no means confidered as excess for men, was certainly too great for a youth of my age. This style of living I continued, when with the regiment, till the latter end of the year 1769, when I had the misfortune to sleep in a damp bed at Sheffield on a journey to York, but arrived there before I felt the ill effects of it. I was then feized with a violent inflammatory rheumatism with great inflammation of my eyes, and was attended by Dr. Dealtry; fo violent was the diforder, that I was bled for it eight times in less than a fortnight; and was three months, before I could consider my health perfectly reestablished. Dr. Dealtry told me, that I should be subject to similar attacks for many years; and that he had no doubt, from the tendency he found in my habit to inflammation, that, when I was farther advanced in life, I should change that complaint for the gout. He predicted truly; for the three fucceeding winters I had the same complaint, but not so violently; the fourth winter I escaped, and imputed my escape to the continuance of cold bathing during the whole of that winter; after that I never escaped it, till I had a regular and severe fit of the gout: after the first attack of rheumatic fever I was more abstemious in my manner of living, though when in company I never subjected myself to any great restraint. In the year 1774 I had quitted the army, and being in a more retired fituation, was feldom led into any excess; in 1776 and 1777 I was in the habit of drinking a good deal of wine very frequently, though not constantly. After that period till the year 1781, I drank a larger quantity of wine regularly, but very feldom to any degree of intoxication. I lived much at that time in the fociety of fome gentlemen, who usually drank nearly a bottle of wine daily after dinner. I must here however observe, that at no part of my life was I accustomed to drink wine in an evening, and very feldom drank any thing more than a fingle half-pint glass of some fort of spirits diluted with much water. Till the year 1781 I had always been accustomed to use very violent and continued exercise on horfe-back; in the winter months I purfued all field diversions, and in the fummer months I rode frequent and long journeys; and with this exercise was liable to perspire to great excess; befides which I was subject to very profuse night-sweats, and had frequently boils break out all over me, especially in the spring and autumn; for which I took no medicine, except a little of the flowers of fulphur with cream of tartar in honey.

"You will observe I bring every thing down to the date of 1781. In the month of October in that year, when I was just entered into the thirty-fecond year of my age, I had the first at-

tack of gout; that fit was very fevere, and of many weeks continuance. I now determined upon a more abstemious method of living, in respect to wine; and indeed the society, in which I had before been accustomed to live, being considerably changed. I had less frequent temptations to excess. From this time I enjoyed the most perfect good state of health till August 1784, when I had my fecond attack of gout. I never perfectly recovered from this attack through the succeeding winter, and in March 1785, was advised to try the Bath waters, and drank them under the direction of one of the faculty of that place. I was there foon feized with a fever, and a flight attack of gout in one knee. I should observe, that when I set out from home, I was in a weak and low state, and unequal to much fatigue; as appeared by my having a fainting fit one day on the road, after having travelled only about fifty miles; in the course of the fummer I had two or three more flight attacks of gout of less confequence, till the month of October; when I was afflicted with it all over me in fuch a manner, as to be without the poffibility of the least degree of removal for some days; and was about two months without being able to get into the air. This was the feverest attack I had then experienced; though I have fince had feveral equally fevere. In the course of this summer I had a fall with my horse; and soon after it, having discovered an enlargement on one elbow, I concluded I had hurt it at that time; but in the course of this last attack having a similar enlargement on the other elbow, I found my mistake, and that they were collections of gouty matter; these increased to the fize of pullet's eggs, and continue in that state. I had soon after similar enlargements on my heels; the right heel being feverely bruifed, I was under the necessity of having it lanced, and a large quantity of chalky matter was discharged from it; and have fince that time frequently had chalky matter taken from it, and sometimes small bits of apparently perfect chalk. My right hand was foon afflicted in the fame way, and I have fcarcely a joint on those fingers now in a natural state. My left hand has escaped tolerably well. After this last attack (viz. October 1785), I had two or three flight attacks before the month of June 1787, when I had a very severe intermittent sever; from that time I continued very well till the latter end of the year, when I began to feel the gout about me very much, but was not confined by it. I was in this state advised to try what is called the American Recipe (gum guaiacum and nitre dissolved in spirits); it had apparently been of effential service to a friend of mine, who from the inability to walk a mile for fome years, was believed to be restored by the use of this medicine to a good state of health, fo as to walk ten miles a day. In addition to this medicine I drank, as my common beverage with my meals, fpruce beer. I had so high an opinion of this medicine in the gout, and of spruce beer as an antiscorbutic, that I contemplated with much fatisfaction, and with very little doubt, the perfect restoration of my health and strength; but I was miserably deceived; for in September 1788 I was seized with the gout in a degree that none but arthritics, and indeed but few of thefe, can easily conceive. From this time till August 1789 I scarcely ever passed a comfortable day; seven months of this time I had been confined, my health feemed much impaired, my strength was diminished, and my appetite almost gone. In this state my friends pressed me to consult you. I was unwilling for some time to do it, as I had lost all hope of relief; however, when I had detrmined to apply to you, I likewise determined to give up every prejudice of my own respecting my case, and to adhere most strictly to your advice. On the 20th of August 1789 I confulted you, on the 25th I entered upon the regimen, which

you prescribed, and which was as follows.

"Drink no malt liquor on any account. Let your beverage at " dinner confift of two glasses of wine diluted with three half-" pints of water. On no account drink any more wine or spir-"ituous liquors in the course of the day; but, if you want more " liquid, take cream and water, or milk and water, or lemonade, "with tea, coffee, chocolate. Use the warm bath twice a week " for half an hour before going to bed, at the degree of heat "which is most grateful to your fensations. Eat meat constant-" ly at dinner, and with any kind of tender vegetables you pleafe. "Keep the body open by two evacuations daily, if possible "without medicine, if not take the fize of a nutmeg of lenitive "electuary occasionally, or five grains of rhubarb every night. "Use no violent exercise, which may subject yourself to sudden " changes from heat to cold; but as much moderate exercise as " may be, without being much fatigued or starved with cold. "Take fome fupper every night; a fmall quantity of animal " food is preferred; but if your palate refuses this, take veger etable food, as fruit-pie, or milk; fomething should be eaten, " as it might be injurious to you to fast too long." To the whole of this I adhered most scrupulously, and soon found my appetite improve, and with it my strength and spirits. I had in December a fevere attack, and two or three flight ones in the course of twelve months; but the improvement in the general state of my health induced me to persevere. On the 18th of August 1790 I had another severe attack, but it went off easier than before, and I foon recovered fufficiently to go to Buxton, which you advised me to, and from which I reaped great benefit; nevertheless on the 29th of December I had a slight attack in comparison of some that I had before experienced, and from that time I was free from gout, and enjoyed my health perfectly well till the fourth week in October 1791; from that till the third week in October 1792; from that till the third week in October 1793; and from that till June 1794. From what happened for the last three years I dreaded the month of October; but I escaped then, and have enjoyed my health most perfectly ever fince till within the last week, that I have had a slight attack in one knee, which is nearly gone, without any symptom to lead me to suppose that it will go further.

"I adhered to your advice most scrupulously for the first year; and in regard to the not drinking malt liquor, and taking only the two glasses of wine with water, I have never deviated but two days; and then the first day I only drank one glass of ale and one glass of champaigne; on the second only one glass of champaigne. With regard to the warm bath, I only use it now when I have gouty symptoms upon me, and in such situations I find it of infinite service; and in other respects I continue to

live according to your direction.

"Many persons have laughed at the idea of my perseverance in a system, which has not been able to cure the gout after sive years' trial; but such persons are either ignorant of what I before suffered, or totally unacquainted with the nature of the disorder. Under the blessing of Providence, by an adherence to your advice, I am reaping all the benefit you slattered me I might expect from it, viz. my attacks less frequent, my sufferings less acute, and an improvement in the general state of my health.

"I have been particular in this account of myfelf at your request, and am, Sir, &c.

Morkey, near Derby, February 10th, 1795.

ROBERT WILMOT."

There are fituations nevertheless in which a paroxysm of gout has been believed to be desirable, as relieving the patient from other disagreeable diseases, or debilities, or sensations. Thus when the liver is torpid, a perpetual uneasiness and depression of spirits occur; which a fit of gout is supposed to cure by a metastasis of the disease. Others have acquired epileptic fits, probably from the disagreeable sensation of a chronically instanted liver; which they suppose the pain and inflammation of gout would relieve. When gouty patients become much debilitated by the progress of the disease, they are liable to dropsy of the Vol. II.

By b

cheft, which they suppose a fit of the gout would relieve. But in all these cases the attempt to procure a paroxysm of gout by wine, or aromatics, or volatiles, or blifters, or mineral waters, feldom succeeds; and the patients are obliged to apply to other methods of relief adapted to other particular cases. In the two former lituations small repeated doses of calomel, or mercurial unction on the region of the liver, may fucceed, by giving new activity to the vessels of the liver, either to secrete or to absorb their adapted fluids, and thus to remove the cause of the gout, rather than to promote a fit of it. In the last case the tincture of digitalis, and afterwards the class of forbentia, must be applied to.

M. M. In young strong patients the gout should be cured by venefection and cathartics and diluents, with poultices externally. But it has a natural crifis by producing calcareous matter on the inflamed membrane, and therefore in old enfecbled people it is fafest to wait for this crisis, attending to the natural evacuations and the degree of fever; and in young ones, where it is not attended with much fever, it is customary and popular not to bleed, but only to keep the body open with aloes, to use gentle sudorifics, as neutral salts, and to give the bark at the decline of the fit; which is particularly useful where the patient is much debilitated. See Arthritis ventriculi, Class I.

2. 4. 6. and Sect. XXV. 17.

Mr. Kelly, furgeon in the navy, in an ingenious treatife, printed at Edinb. 1797, termed Observations on Compression by the Tourniquet, advises in both inflammatory and chronic rheumatism to compress the artery of the affected limb by the tourniquet, for 15 or 20 minutes, relaxing or tightening the bandage, as the patient feems to bear it. And in inflammatory rheumatism, he advises to take blood from a vein below the bandage, which he fays relieves the pain and destroys the inflammation. Could not this experiment be used safely in the gout of young or ftrong patients? and perhaps with speedy

When there is not much fever, and the patient is debilitated with age, or the continuance of the difease, a moderate opiate, as twenty drops of tincture of opium, or one grain of folid opium, may be taken every night with advantage. Externally a paste made with double the quantity of yest is a good poultice; and booterkins made with oiled filk, as they confine the perspirable matter, keep the part moist and supple, and thence relieve the pain like poultices.

The only fafe way of moderating the disease is by an uniform and equal diminution, or a total abstinence from fermented liquors, with the cautions directed in Sect. XII. 7. 8. The continued use of strong bitters, as of Portland's powder, or bark, has been frequently injurious, as spoken of in the Materia Med-

ica, Art. IV. 2. 11.

One of my acquaintance, who was much afflicted with the gout, abstained for about half a year from beer and wine; and not having resolution to persist, returned to his former habits of potation in less quantity; and observed that he was then for one winter stronger and freer from the gout than usual. This however did not long continue, as the disease afterwards returned with its usual or increased violence. This I think is a circumstance not unlikely to occur, as opium has a greater effect after its use has been a while intermitted; and the debility or torpor, which is the cause of gout, is thus for a few months prevented by the greater irritability of the system, acquired during the lessened use of fermented liquor.

For the fame reason an ounce of spirituous tincture of guaiacum, or of bark, is said to have for some time prevented returns of the gout; which has afterwards, like all other great stimuli when long continued, been succeeded by greater debility, and destroyed the patient. This seems to have been exemplified in the case of the ingenious Dr. Brown, see Presace to his Elementa Medicinæ; he found temporary relief from the stimulus

of wine, regardless of its future effects.

Lastly, as the gouty inflammation, like the rheumatic swellings of the wrists and ankles, is not a primary disease; and is like them not liable to suppurate; there is reason to believe that opiates may be given with less danger than in other inflammations, and with a prospect of advantage; since by preventing the periods of torpor of the liver, or other part, primarily affected, the diurnal additional attack, or its producing inflammation of another limb, may sometimes be prevented. A person a few days ago assured me, that when the gout came into his foot, his practice was to take thirty drops of tincture of opium; and in half an hour thirty drops more; and even a third dose, if the pain did not subside; and that the fit soon ceased. I should think this a dangerous experiment. A Mr. Warner wrote a book recommending opium in the gout, but died soon after its publication.

16. Rheumatismus. Acute rheumatism. There is reason to suspect, that rheumatic inflammations, like the gouty ones, are not a primary disease; but that they are the consequence of a translation of morbid action from one part of the system to another. This idea is countenanced by the frequent change of place of rheumatic-like gouty inflammations, and from their at-

tacking two fimilar parts at the fame time, as both ankles and both wrifts, and these attacks being in succession to each other. Whereas it is not probable that both feet or both hands should at the fame time be equally exposed to any external cause of the difease, as to cold or moisture; and less so that these should occur in succession. Lastly, from the inflammatory diathesis in this difease being more difficult to subdue, and more dangerous in event, than other common inflammations, especially to pregnant women, and in weak constitutions.

From this idea of the rheumatism being not a primary disease, like the gout, but a transferred morbid action owing to the previous torpor of some other part of the system, we perceive why it attacks weak people with greater pertinacity than strong ones; refifting or recurring again and again after frequent evacuations, in a manner very different from primary inflammations : because the cause is not removed, which is at a distance from the

feat of the inflanimation.

This also accounts for rheumatic inflammations fo very rarely terminating in suppuration, because like the gout the original cause is not in the inflamed part, and therefore does not continue to act after the inflammation commences. Instead of suppuration in this difease, as well as in the gout, a quantity of mucus or coagulable lymph is formed on the inflamed membrane; which in the gout changes into chalk-stones, and in the rheumatism is either reabsorbed, or lies on the membrane, producing pains on motion long after the termination of the inflammation, which pains are called chronic rheumatism. The membranes, which have thus been once or repeatedly inflamed, become less mobile, or less liable to be affected by sympathy, as appears by the gout affecting new parts, when the joints of the foot have been frequently inflamed by it; hence as the cause of the inflammation does not exist in the inflamed part, and as this part becomes less liable to future attacks, it feldom suppurates.

Pleurodyne rheumatica. When rheumatism affects the muscles of the chest, it produces symptoms similar to pleurify, but diftinguished from it by the patient having previously suffered rheumatic affections in other parts, and by the pertinacity or continuance of the inflammatory state of the patient.

This should be termed pleurodyne rheumatica.

Enteralgia rheumatica. When rheumatic inflammation affects the bowels, it produces a difease very different from enteritis, or common inflammation of the bowels, and should be termed interalgia rheumatica. The pain is less than in enteritis, and the disease of longer continuance, with harder pulse, and the blood equally fizy. It is attended with frequent dejections, with much mucus, and previous griping pains, but without vomiting; and differs perhaps from dyfentery from its not being attended with bloody flools, and not being infectious.

Rheumatic inflammations, which I believe to arise from the fympathy of the inflamed part with the torpor of some distant part, may I think be certainly distinguished from those inflammations of the same part, which have not arisen from sympathy with the torpor of some distant part, but where the cause of the inflammation began in the part where the inflammation exists, by this circumstance; that in rheumatic inflammation the hard or sharp pulse continues at about 118 in a minute after the pain abates or ceases. Whereas in the latter the inflammatory sever ceases along with the pain.

In two cases of pain of the side, and difficult respiration, which I esteemed rheumatic, as the hard pulse of 118 with sized blood continued after repeated venesection, gentle cathartics, and mild antimonials, I found ten drops of saturated tincture of digitalis given every six hours appear to produce great good effect, and to abate and remove the instammatory diathesis in three

or four days.

Hence when a fever has continued more than one lunar period, attended with a hard or sharp pulse of 118 or 120 in a minute, and is not attended with cough or symptoms of absorbed matter, it may be esteemed of rheumatic origin, though no local pain or inflammation at present exists; and this with greater certainty, if pain had previously existed: for no severs, except the hectic severs from absorbed matter, and this attended with inslammatory diathesis, and which may be called rheumatic, ever properly extend, I believe, beyond one lunation; though symptoms of debility may continue a while longer. This observation is worth attending to in practice, as it distinguishes the kind of sever, in which when the bark is erroneously given, it does no service, and in which I believe saturated tincture of digitalis given as above to be the most efficacious medicine.

Rheumatismus suppurans. There is another kind of rheumatism attended with debility, which suppurates, and should be termed rheumatismus suppurans. It is generally believed to be the gout, till suppuration takes place on the swelled joint; and, as the patient sinks, there are sloughs formed over the whole mouth; and he seems to be destroyed by inflammation or gangrene of the mucous membranes. I have twice seen this disease in patients about sixty. Some other diseases are erroneously called rheumatic, as hemicrania, and odontalgia. See Sect.

XXVII 3v

M. M. In the three former kinds venefection repeatedly. Ca-

thartics. Antimonials. Diluents. Neutral falts. Oil. Warm bath. Afterwards the bark. Opium with or without ipecacuanha; but not till the patient is confiderably weakened. Sweats forced early in the difease do injury. Opium given early in the disease prolongs it. In the last kind, gentle stimulants, as

wine and water, mucilage, forbentia.

In acute rheumatism, when the swelling of the joints first affected subsides, a return of torpor in the part primarily diseased commences previous to an inflammation of the joints fecondarily affected. Hence when the tumor of the joints first affected fublides, half a grain of opium, every night, and Peruvian bark, or other bitter medicine, may be given to prevent this return of torpor with great advantage; if the patient has previously been properly evacuated, and is not now too much inflamed.

Dr. Fordyce afferts, that when it was the practice to bleed largely in acute rheumatifm, a metaftafis frequently took place to the interior parts of the body, and destroyed the patient. And adds, that during the last fifteen years of his practice this has rarely happened, as he has entirely left off bleeding in the acute rheumatism. Third differtation on fever by G. Fordyce, M. D. London, Johnson. On this subject it may be remarked, that as rheumatism like gout is a secondary disease, the inflammation of one part being symptomatic, the feat of torpor existing in fome other part, it may not be fo constantly necessary to bleed fo copiously in those secondary inflammatory diseases, as in those primary ones, where the inflamed part was previously the feat of torpor, as in pleurify, peripneumony, and interitis; but in rheumatism, as well as in ervsipelas, I am convinced, that where the inflammation of the fystem is great, repeated venesection is not only useful; but that those, who perish by either of those difeases, perish for the want of venesection early, where the attack is violent. And lastly, that even in the gout of young and strong stubjects, as I know by experience on myself, a moderate venefection shortens the fit, and lessens I believe the hazard of metastasis.

The following is a case of suppurative rheumatism. Mr. F-, about fixty, was supposed to have the gout in his hand, which however suppurated, and it was then called the suppumtive rheumatism. He had lived rather intemperately in respect to wine, and was now afflicted with a tendency to inflammation of the mucous membranes. As he lay on the bed half refupine, propped up with pillows, and also slept in 'that posture, his lower jaw dropped by its own weight, when the voluntary power of the muscles was suspended. The mucus of his mouth and throat became quite dry, and at length was succeeded by sloughs;

this was a most distressing circumstance to him, and was in vain endeavoured to be relieved by supporting his jaw by slender fleel fprings fixed to his night-cap, and by fprings of elastic gum. The floughs spread and seemed to accelerate his death. See Class I. 1. 2. 2.

In acute rheumatism Mr. Kellie afferts that he has had great fuccess by putting a tourniquet on the affected limb, so as to compress the artery, and then by taking blood from a vein below the bandage, as mentioned above in Podagra. Class IV. 1. 2. 15.

17. Erylipelas. The erylipelas differs from the zona ignea. and other species of herpes, in its being attended with fever. which is fometimes of the fensitive irritated or inflammatory kind, with strong and full pulse; and at other times with weak pulse and great inirritability, as when it precedes or attends mortifications. See Class II. 1. 3. 2.

Like the zona ignea above described, it seems to be a secondary difease, having for its primary part the torpor or inflammation of fome internal or distant membrane, as appears from its fo frequently attending wounds; fometimes spreading from iffues over the whole limb, or back, by fympathy with a tendon or membrane, which is stimulated by the pease in them. In its more violent degree I suppose that it sympathizes with some extensive internal membranes, as of the liver, stomach, or brain. Another reason, which countenances this idea, is, that the inflammation gradually changes its fituation, one part healing as another inflames; as happens in respect to more distant parts in gout and rheumatism; and which feems to shew, that the cause of the disease is not in the same place with the inflammation. And thirdly, because the erysipelas of the face and head is liable to affect the memb ranes of the brain; which were probably in these cases the original or primary seat of the disease; and lastly, because the fits of erysipelas, like those of the gout, are liable to return at certain annual or monthly periods, as further treated of in Class II. 1. 3. 2.

Many cases of erysipelas from wounds or bruises are related in Default's Surgical Journal, Vol. II. in which poultices are faid to do great injury, as well as oily or fatty applications. Saturnine folutions were fometimes used with advantage. A grain of emetic tartar given to clear the stomach and bowels, is

faid to be of great fervice.

18. Testium tumor in gonorrhæa. Mr. Hunter in his Treatise on the Venereal Disease observes, that the tumor of the testes in gonorrhœa arises from their sympathy with the inflammation of the urethra; and that they are not fimilar to the actions arifing from the application of venereal matter, whether by abforption

or otherwise; as they seldom or never suppurate; and when Suppuration happens, the matter produced is not venereal. Trea-

tise on Venereal Disease, p. 53.

19. Testium tumor in parotidite. The sympathy between some parts about the throat and the genitals has been treated of in Class IV. 1. 2. 7. The swelling of the testes, when that of the parotis subsides, seems to arise from the affociation of successive action; as the tension of the penis in hydrophobia appears to arise from the previous synchronous affociations of the sensitive motions of these parts; but the manner of the production of both these affociations is yet very obscure. In women a swelling of the breafts often succeeds the decline of the mumps by another wonderful fympathy. See Class IV. 1. 2. 7. and 1. 1. 2. 15. In many persons a delirium succeeds the swelling of the parotis, or the subsequent ones of the testes or breafts; which is fometimes fatal, and feems to arise from a sympathy of fuccessive action, and not of fynchronous action, of the membranes of the brain with those of the parotid glands. Sometimes a stupor comes on instead of this delirium, which is relieved by fomenting the shaved head for an hour or two. See Class II. 1. 3. 4.

Increased Associate Motions.

GENUS III.

Catenated with Voluntary Motions.

SPECIES.

1. Deglutitio invita. When any one is told not to swallow his faliva, and that especially if his throat be a little fore, he finds a necessity of immediately swallowing it; and this the more certainly, the more he voluntarily endeavours not to do so.

In this case the voluntary power exerted by our attention to the pharynx renders it more sensible to irritation, and therefore occasions it to be more frequently induced to swallow the saliva. Here the irritation induces a volition to swallow it, which is more powerful than the desire not to swallow it. See XXIV.

1. 7. So in reverie, when the voluntary power was exerted on any of the senses, as of sight or taste, the objects of those senses became perceived; but not otherwise. Sect. XIX. 6. This is a troublesome symptom in some fore throats.

M. M. Mucilage, as sugar and gum arabic.

Warm water held in the mouth frequently, a fomentation to the inflamed throat.

2. Nicitatio invita. Involuntary winking with the eye-lids, and twitchings of the face, are originally induced by an endeavour to relieve fome difagreeable fensations about inflamed eyes, as the dazzling of light; and afterwards these motions become catenated with other motions or sensations, so as not to be governed by the will. Here the irritation first produces a volition to wink, which by habit becomes stronger than the anti-volition not to wink.

This fubject is rendered difficult from the common acceptation of the word, volition, including previous deliberation, as well as the voluntary exertion, which fucceeds it. In the volitions here spoken of there is no time for deliberation or choice of objects, but the voluntary act immediately succeeds the fenfation which excites it.

M. M. Cover the affected parts with a flicking plaster or a blister. Pass a fine needle and thread through a part of the skin over the muscle, which moves, and attach the other end of

Vol. II. Ccc the

the thread by a sticking plaster to a distant part. An issue behind the ear. To practife daily by a looking-glass to stop the motions with the hand. See the cure of a case of the leaping of a muscle of the arm, Sect. XVII. 1. 8. See Convulsio debilis, Class III. 1. 1. 5. Frequent electric sparks, or very slight shocks.

3. Rifus invitus. Involuntary laughter. When the pleasure arising from new combinations of words and ideas, as in puns; or of other circumstances, which are so trivial, as to induce no voluntary exertion to compare or consider their present importance or their future consequence; the pleasure is liable to rise into pain; that is, the ideas or fensual motions become exerted too violently for want of some antithesistic ideas; in the same manner as those muscles, which have weak antagonists, as those of the calf of the leg, are liable to fall into cramp or painful contraction. In this situation a scream is begun to relieve this pain of ideas too violently exerted, which is stopped again soon, as explained in Sect. XXXIV. 1. 4. and Class III. 1. 1. 4. and IV. 2. 3. 3.

The pain, into which this pleasure rises, which would excite the scream of laughter, has been felt forcibly by every one; when they have been under such circumstances, as have induced them to restrain it by a counter-volition; till at length the increased associate motions produce so much pain as to overcome the counter-volition, and the patient bursts out into indecent laughter, contrary to his will in the common acceptation of

that word.

4. Lufus digitorum invitus. An awkward playing with the fingers in fpeaking in public. These habits are begun through bashfulness, and seem rather at first designed to engage the attention in part, and thus prevent the disagreeable ideas of mauvaise honte; as timorous boys whistle, when they are obliged to walk in the dark; and as it is sometimes necessary to employ raw soldiers in perpetual manœuvres, as they advance to the first charge.

5. Unguium morfiuncula invita. Biting the nails is a deprayed habit arifing from fimilar causes as those of the last arti-

cle.

M. M. Dip the fingers in folution of aloes.

6. Vigilia invita. Watchfulness, where the person wishes and endeavours to fall asleep, properly belongs to this place, as the wish or volition to sleep prevents the desired effect; because sleep consists in an abolition of volition. See Class III. 1.2.3.

ORDO I.

Increased Associate Motions.

GENUS IV.

Catenated with External Influences,

SPECIES.

1. Vita ovi. Life of an egg. The eggs of fowls were shewn by Mr. J. Hunter to resist the freezing process in their living state more powerfully than when they were killed by having the yolk and white shook together. Philos. Trans. It may be asked, does the heat during the incubation of eggs act as a stimulus exciting the living principle into activity? Or does it act fimply as a causa sine quâ non, as an influence, which penetrating the mass, removes the particles of it to a greater distance from each other, fo as to allow their movement over each other, in the fame manner as heat is conceived to produce the fluidity of water; not by stimulus, but by its penetrating influence? Or may elementary heat in its uncombined state be supposed to act only as an influence necessary to life in its natural quantity; whence torpor and death follow the eduction of it from the body; but in its increased state above what is natural, or usual, that it acts as a stimulus; which we have a sense to perceive; and which excites many parts of the fystem into unnatural action? See Class IV. I. I. C.

2. Vita biemi-dormientium. The torpor of infects, and birds, and quadrupeds, during the cold feafon, has been called fleep; but I suppose it must differ very much from that state of animal life, since not only all voluntary power is suspended, but sensation and vascular motion have geased, and can only be restored by the influence of heat. There have been related instances of snails, which have recovered life and motion on being put into water after having experienced many years of torpidity, or apparent death, in the cabinets of the curious. Here the water as well as the heat are required not only as a stimulus, but as a causa sine quanto of fluidity and motion, and consequent life.

3. Pullulatio arborum. The annual revivescence of the buds of trees seems not only to be owing to the influence of the returning warmth of the spring, but also to be catenated with solar gravitation; because seeds and roots and buds, which are analogous to the eggs of animals, put forth their shoots by a less

quantity

quantity of heat in fpring, than they had undergone in the latter part of autumn, which may however be ascribed to their previous torpid state, and confequent accumulation of sensorial power, or irritability; as explained in Botanic Garden, Part II. Cant. I. 1. 322. note. Other circumstances, which counter nance the idea, that vegetation is affected by folar gravitation, as well as by heat, may be observed in the ripening of the feeds of plants both in those countries where the summers are short, and in those where they are long. And by some flowers closing their bells at noon, or foon after; and hence feem to fleep rather at folar diurnal periods, than from the influence of cold, or the deficiency of light.

4. Orgafinatis venerei periodus. The venereal orgafm of birds and quadrupeds commences or returns about the vernal or autumnal equinoxes, and thence feems in respect to their great periods to be governed by folar influence. But if this orgafm be disappointed of its object, it is said to recur at about monthly periods, as observed in mares and bitches, in this respect refembling the female catamenia. See Sect. XXXVI. 2. 3. and

Sect. XVI. 13.

5. Brachii concussio electrica. The movement of the arm, even of a paralytic patient, when an electric shock is passed through it, is owing to the stimulus of the excess of electricity. When a piece of zinc and another of filver, each about the fize of a crown-piece, are placed one under the upper lip, and the other on the tongue, so as the outer edges may be brought into contact, there is an appearance of light in the eyes, as often as the outer edges of these metals are brought into contact or separated; which is another instance of the stimulus of the passage of electric shocks through the fibres of the organs of sense, as well as through the muscular fibres. See Sect. XII. 1. 1. But in its natural state electricity seems only to act as an influence on animal and vegetable bodies; of the falutary or injurious effects of which we have yet no precise knowledge.

Yet if regular journals were kept of the variations of atmofpheric electricity, it is probable some discoveries of its influence on our system might in time be discovered. For this purpose a machine on the principle of Mr. Bennet's electric doubler might be applied to the pendulum of a clock, fo as to manifest, and even to record the daily or hourly variations of aerial electricity. Which has already been executed, and applied to the pendulum of a Dutch wooden clock, by Mr. Bennet, curate of Wirkf-

worth in Derbyshire.

Besides the variations of the degree or kind of atmospheric electricity, some animals, and some men, seem to possess a greatof which a famous history of a Russian prince was lately published; who, during the clear and severe frosts of that country, could not move himself in bed without luminous corruscations. Such may have been the case of those people, who have been related to have taken fire spontaneously, and to have been reduced to ashes. The electric concussion from the gymnotus electricus, and torpedo, are other instances of the power of the animal system to accumulate electricity, as in these it is used as a weapon of defence, or for the purpose of taking their prey.

Some have believed that the accumulation or passage of the magnetic sluid might affect the animal system, and have asserted that the application of a large magnet to an aching tooth has quickly effected a cure. If this experiment is again tried in odontalgia, or hemicrania, the painful membrane of the tooth or head should be included between the south and north poles of a horse-shoe magnet, or between the contrary poles of two different magnets, that the magnetism may be accumulated on

the torpid part.

6. Oxygenatio fanguinis. The variation of the quantity of oxygen gas existing in the atmosphere must affect all breathing animals; in its excess this too must be esteemed a stimulus; but in its natural quantity would seem to act as an influence, or cause, without which animal life cannot exist even a minute. It is hoped that Dr. Beddoes's plan for a pneumatic infirmary, for the purpose of putting this and various other airs to the test of experiment, will meet with public encouragement, and render consumption, asthma, cancer, and many diseases conquerable, which at present prey with unremitted devastation on all orders and ages of mankind.

7. Humedatio corporis. Water, and probably the vapour of water dissolved or dissufed in the atmosphere, unites by mechanical attraction with the unorganized cuticle, and softens and enlarges it; as may be seen in the loose and wrinkled skin of the hands of washerwomen; the same probably occurs to the mucous membrane of the lungs in moist weather; and by thickening it increases the dissipation of some people, who are said to be asthmatical. So far water may be said to act as an influx or influence, but when it is taken up by the mouths of the absorbent system, it must excite those mouths into

action, and then acts as a stimulus.

There appears from hence to be four methods by which animal bodies are penetrated by external things. 1. By their stimulus, which induces the absorbent vessels to imbibe them. 2. By mechanical attraction, as when water softens the cuticle. 3. By

chemical

chemical attraction, as when oxygen passes through the membranes of the air-vessels of the lungs, and combines with the blood. And lastly, by instruction, without mechanical attraction, chemical combination, or animal absorption, as the universal sluids of heat, gravitation, electricity, magnetism, and perhaps of other etherial sluids yet unknown.

A STATE OF THE PARTY OF THE PAR

ORDO II.

Decreased Associate Motions.

GENUS I.

Catenated with irritative Motions.

As irritative muscular motions are attended with pain, when they are exerted too weakly, as well as when they are exerted too strongly; so irritative ideas become attended with sensation when they are exerted too weakly, as well as when they are exerted too strongly. Which accounts for these ideas being attended with sensation in the various kinds of vertigo described below.

There is great difficulty in tracing the immediate cause of the deficiencies of action of some links of the affociations of irritative motions; first, because the trains and tribes of motions, which compose these links, are so widely extended as to embrace almost the whole animal system; and secondly, because when the first link of an affociated train of actions is exerted with too great energy, the second link by reverse sympathy may be affected with torpor. And then this second link may transsmit, as it were, this torpor to a third link, and at the same time regain its own energy of action; and it is possible this third link may in like manner transsmit its torpor to a fourth, and thus regain

its own natural quantity of motion.

I shall endeavour to explain this by an example taken from sensitive affociated motions, as the origin of their disturbed actions is more easily detected. This morning I saw an elderly person, who had gradually lost all the teeth in his upper jaw, and all of the under except three of the molares; the last of these was now loose, and occasionally painful; the fangs of which were almost naked, the gums being much wasted both within and without the jaw. He is a man of attentive observation, and affured me, that he had again and again noticed, that, when a pain commenced in the membranes of the alveolar process of the upper jaw opposite to the loose tooth in the under one (which had frequently occurred for feveral days past) the pain of the loofe tooth ceased. And that, when the pain afterwards extended to the ear and temple on that side, the pain in the membranes of the upper jaw ceased. In this case the membranes of the alveolar process of the upper jaw became torpid, and confequently painful, by their reverse sympathy with the too violent actions of the inflamed membranes of the loofe tooth; and then by a fecondary fympathy the membranes about the ear and temple became torpid, and painful; and those of the alveolar process of the upper jaw regained their natural quantity of action, and ceased to be painful. A great many more nice and attentive observations are wanted to elucidate these curious circumstances of association, which will be found to be of the greatest importance in the cure of many diseases, and lead us to the knowledge of sever.

SPECIES.

1. Cutis frigida pransorum. Chillness after dinner frequently attends weak people, or those who have been exhausted by exercise; it arises from the great expenditure of the sensorial power on the organs of digestion, which are stimulated into violent action by the aliment; and the vessels of the skin, which are affociated with them, become in some measure torpid by reverse sympathy; and a consequent chillness succeeds with less absorption of atmospheric moisture. See the subsequent article.

- 2. Pallor urina pransarum. The paleness of urine after a full meal is an instance of reverse association; where the secondary part of a train of associate motions acts with less energy in consequence of the greater exertions of the primary part. After dinner the absorbent vessels of the stomach and intestines are stimulated into greater action, and drink up the newly taken aliment; while those, which are spread in great number on the neck of the bladder, absorb less of the aqueous part of the urine than usual, which is therefore discharged in a more dilute state; and has been termed crude by some medical writers, but it only indicates, that so great a proportion of the sensorial power is expended on digestion and absorption of the aliment, that other parts of the system act for a time with less energy. See Class IV.
- 3. Pallor urine a frigore cutaneo. There is a temporary difcharge of pale water, and a diarrhoea, induced by exposing the skin to the cold air; as is experienced by boys, who strip themfelves before bathing. In this case the mouths of the cutaneous lymphatics become torpid by the subduction of their accustomed degree of heat, and those of the bladder and intestines become torpid by direct sympathy; whence less of the thinner part of the urinary secretion, and of the mucus of the intestines, is reabsorbed. See Sect. XXIX. 4. 6. This effect of suddenly cooling the skin by the aspersion of cold water has been used with success in costiveness, and has produced evacuations, when

other means have failed. When young infants are afflicted with griping joined with costiveness, I have sometimes directed them to be taken out of a warm bed, and carried about for a few minutes in a cool room, with almost instant relief.

- 4. Pallor ex agritudine. When sickness of stomach first occurs, a paleness of the skin attends it; which is owing to the affociation or catenation between the capillaries of the stomach and the cutaneous ones; which at first act by direct sympathy. But in a short time there commences an accumulation of the sensorial power of affociation in the cutaneous capillaries during their state of inactivity, and then the skin begins to glow, and sweats break out, from the increased actions of the cutaneous glands or capillaries, which is now in reverse sympathy with those of the stomach. So in continued severs, when the stomach is totally torpid, which is known by the total aversion to solid food, the cutaneous capillaries are by reverse sympathy in a perpetual state of increased activity, as appears from the heat of the skin.
- 5. Dyspnæa a balneo frigido. The difficulty of breathing on going up to the middle in cold water is owing to the irritative affociation or catenation of the action of the extreme vessels of the lungs with those of the skin. So that when the latter are rendered torpid or inactive by the application of fudden cold, the former become inactive at the fame time, and retard the circulation of the blood through the lungs, for this difficulty of breathing cannot be owing to the pressure of the water impeding the circulation downwards, as it happens equally by a cold shower-bath, and is foon conquered by habitual immersions. The capillaries of the skin are rendered torpid by the subduction of the stimulus of heat, and by the consequent diminutions of the sensorial power of irritation. The capillaries of the lungs are rendered torpid by the diminution of the sensorial power of affociation, which is now excited in less quantity by the lessened actions of the capillaries of the skin, with which they are catenated. So that at this time both the cutaneous and pulmonary capillaries are principally actuated, as far as they have any action, by the stimulus of the blood. But in a short time the fenforial powers of irritation, and of affociation, become accumulated, and very energetic action of both these membranes fucceeds. Which thus refemble the cold and hot fit of an intermittent fever.
- 6. Dyspepsia a pedibus frigidis. When the feet are long cold, as in riding in cold and wet weather, some people are very liable to indigestion and consequent heart-burn. The irritative motions of the stomach become torpid, and do their office of di-

Vol. II. D D d gestion

gestion imperfectly, in consequence of their association with the torpid motions of the vessels of the extremities. Fear, as it produces paleness and torpidity of the skin, frequently occasions temporary indigestion in consequence of this affociation of the vesfels of the skin with those of the stomach; as riding in very bad roads will give flatulency and indigestion to timorous people.

A short exposure to cold air increases digestion, which is then owing to the reverse sympathy between the capillary vessels of the skin, and of the stomach. Hence when the body is exposed to cold air, within certain limits of time and quantity, a reverfe fympathy of the stomach and the skin first occurs, and afterwards a direct sympathy. In the former case the expenditure of fenforial power by the skin being lessened, but not its production in the brain; the second link of the association, viz. the stomach, acquires a greater share of it. In the latter case, by the continuation of the deficient stimulus of heat, the torpor becomes extended to the brain itself, or to the trunks of the nerves; and univerfal inactivity follows.

7. Tussis a pedibus frigidis. On standing with the feet in thawing fnow, many people are liable to inceffant coughing. From the torpidity of the absorbent vessels of the lungs, in con-

fequence of their irritative affociations with those of the skin. they cease to absorb the faline part of the secreted mucus; anda cough is thus induced by the irritation of this faline fecretion; which is similar to that from the nostrils in frosty weather, but differs in respect to its immediate cause; the former being from affociation with a distant part, and the latter from defect of the stimulus of heat on the nostrils themselves. See Catarrhus

frigidus, Class I. 2. 3. 3.

8. Tuffis hepatica. The cough of inebriates, which attends the enlargement of the liver, or a chronical inflammation of its upper membrane, is supposed to be produced by the inconvenience the diaphragm fuffers from the compression or heat of the liver. It differs however effentially from that attending hepatitis, from its not being accompanied with fever. And is perhaps rather owing to irritative affociation, or reverse sympathy, between the lungs and the liver. As occurs in sheep, which are liable to a perpetual dry cough, when the fluke-worm is preying on the substance of their livers. See Class II. 1. 1. 5.

M. M. From half a grain to a grain of opium twice a day. A drachm of mercurial ointment rubbed on the region of the

liver every night for eight or ten times.

9. Tussis arthritica. Gout-cough. I have feen a cough, which twice recurred at a few years distance in the same perfon, during his fits of the gout, with fuch pertinacity and violence as to refift venefection, opiates, bark, blifters, mucilages, and all the usual methods employed in coughs. It was for a time supposed to be the hooping-cough, from the violence of the action of coughing; it continued two or three weeks, the patient never being able to sleep more than a few minutes at once during the whole time, and being propped up in bed with pil-

lows night and day.

As no fever attended this violent cough, and but little expectoration, and that of a thin and frothy kind, I suspected the membrane of the lungs to be rather torpid than inflamed, and that the faline part of the mucus not being absorbed stimulated them into perpetual exertion. And lastly, that though the lungs are not sensible to cold and heat, and probably therefore less mobile, yet, as they are nevertheless liable to consent with the torpor of cold feet, as described in Species 6 of this Genus, I suspected this torpor of the lungs to succeed the gout in the feet, or to act a vicarious part for them.

10. Vertigo rotatoria. In the vertigo from circumgyration the irritative motions of vision are increased; which is evinced from the pleasure that children receive on being rocked in a cradle, or by fwinging on a rope. For whenever fenfation arifes from the production of irritative motion with less energy than natural, it is of the difagreeable kind, as from cold or hunger; but when it arises from their production with greater energy than natural, if it be confined within certain limits, it is of the pleafurable kind, as by warmth or wine. With these increafed irritative motions of vision, I suppose those of the stomach are performed with greater energy by direct sympathy; but when the rotatory motions, which produce this agreeable vertigo, are continued too long, or are too violent, fickness of the ftomach follows; which is owing to the decreased action of that organ from its reverse sympathy with the increased actions of the organ of vision. For the expenditure of sensorial power by the organ of vision is always very great, as appears by the fize of the optic nerves; and is now so much increased as to deprive the next link of affociation of its due share. As mentioned in

Species 6 of this Genus.

In the fame manner the undulations of water, or the motions of a ship, at first give pleasure by increasing the irritative motions belonging to the sense of vision; but produce sickness at length by expending on one part of the affociated train of irritative actions too much of that sensorial power, which usually served the whole of it; whence some other parts of the train acquire too little of it, and perform their actions in consequence too seebly, and thence become attended with disagreeable sensation.

It must also be observed, that when the irritative motions are stimulated into unusual action, as in inebriation, they become fucceeded by fenfation, either of the pleafurable or painful kind; and thus a new link is introduced between the irritative motions thus excited, and those which used to succeed them: whence the affociation is either differenced or much weakened. and thus the vomiting in fea-fickness occurs from the defect of the power of affociation, rather than from the general deficiency

of fenforial power.

When a blind man turns round, or when one, who is not blind, revolves in the dark, a vertigo is produced belonging to the fense of touch. A blind man balances himself by the fense of touch, which being a less perfect means of determining small quantities of deviation from the perpendicular, occasions him to walk more carefully upright than those, who balance themselves by vision. When he revolves, the irritative affociations of the muscular motions, which were used to preserve his perpendicularity, become difordered by their new modes of fuccessive exertion; and he begins to fall. For his feet now touch the floor in manners or directions different from those they have been accustomed to; and in consequence he judges less perfectly of the fituation of the parts of the floor in respect to that of his own body, and thus loses his perpendicular attitude. This may be illustrated by the curious experiment of crossing one finger over the next to it, and feeling a nut or bullet with the ends of them. When, if the eyes be closed, the nut or bullet appears to be two. from the deception of the sense of touch.

In this vertigo from gyration, both of the fense of fight, and of the fense of touch, the primary link of the affociated irritative motions is increased in energy, and the secondary ones are increafed at first by direct sympathy; but after a time they become decreased by reverse sympathy with the primary link, owing to the exhaustion of sensorial power in general, or to the power of affociation in particular; because in the last case, either pleasurable or painful fensation has been introduced between the links of a train of irritative motions, and has different, or much en-

feebled them.

Dr. Smyth, in his Effay on Swinging in Pulmonary Confumption, has observed, that swinging makes the pulse flower. Dr. Ewart of Bath confirmed this observation both on himself and on Col. Cathcart, who was then hectic, and that even on shipboard, where some degree of vertigo might be supposed previoully to exist. Dr. Currie of Liverpool not only confirmed this observation frequently on himself, when he was also phthisical, but found that equitation had a fimilar effect on him, uniformly retarding his pulse. This curious circumstance cannot arise from the general effect of exercise, or fatigue, as in those cases the pulse becomes weaker and quicker; it must therefore be ascribed to a degree of vertigo, which attends all those modes of motion, which we are not perpetually accustomed to.

Dr. Currie has further observed, that "in cases of great debility the voluntary muscular exertion requisite in a swing produces weariness, that is, increases debility; and that in such instances he had frequently noticed, that the diminution of the frequency of the pulse did not take place, but the contrary." These

circumstances may thus be accounted for.

The links of affociation, which are effected in the vertigo occasioned by unufual motion, are the irritative motions of the fense of vision, those of the stomach, and those of the heart and arteries. When the irritative ideas of vision are exerted with greater energy at the beginning of vertigo, a degree of sensation is excited, which is of the pleasurable kind, as above mentioned; whence the associated trains of irritative motions of the stomach, and heart, and arteries, act at first with greater energy, both by direct sympathy, and by the additional sensorial power of sensation. Whence the pulse of a consumptive patient becomes stronger and consequently slower.

But if this vertigo becomes much greater in degree or duration, the first link of this train of affociated irritative motions expends too much of the sensorial power, which was usually employed on the whole train; and the motions of the stomach become in consequence exerted with less energy. This appears, because in this degree of vertigo sickness supervenes, as in seasickness, which has been shewn to be owing to less energetic action of the stomach. And the motions of the heart and arteries then become weaker, and in consequence more frequent, by their direct sympathy with the lessened actions of the stomach. See Supplement, I. 12. and Class II. 1. 6. 7. The general weakness from satigue is owing to a similar cause, that is, to the too great expenditure of sensorial power in the increased actions of one part of the system, and the consequent desiciency of it in other parts, or in the whole.

The abatement of the heat of the skin in hectic fever by swinging, is not only owing to the increased ventilation of cool air, but to the reverse sympathy of the motions of the cutaneous capillaries with those of the heart and arteries; which occurs in all fevers with arterial debility, and a hot or dry skin. Hence during moderate swinging the action of the heart and arteries becomes stronger and slower, and the action of the capillaries, which was before too great, as appeared by the heat of the skin,

is now lessened by their reverse sympathy with that of the heart

and arteries. See Supplement, I. 8.

11. Vertigo vifualis. Vifual vertigo. The vertigo rotatoria described above, was induced by the rotation or undulation of external objects, and was attended with increased action of the primary link of the affociated motions belonging to vision, and with confequent pleafure. The vertigo vifualis is owing to less perfect vision, and is not accompanied with pleasurable fensation. This frequently occurs in strokes of the palfy, and is then fucceeded by vomiting; it fometimes precedes epileptic fits, and often attends those, whose fight begins to be impaired by age.

In this vertigo the irritative ideas of the apparent motions of objects are less distinct, and on that account are not succeeded by their usual irritative affociations of motion; but excite our attention. Whence the objects appear to librate or circulate according to the motions of our heads, which is called dizziness: and we lofe the means of balancing ourselves, or preserving our perpendicularity, by vision. So that in this vertigo the motions of the affociated organs are decreafed by direct sympathy with their primary link of irritation; as in the preceding case of sea-

fickness they are decreased by reverse sympathy.

When vertigo affects people about fifty years of age, their fight has generally been fuddenly impaired; and from their lefs accurate vision they do not soon enough perceive the apparent motions of objects; like a person in a room, the walls of which are stained with the uniform figures of lozenges, explained in Sect. XX. 1. This is generally ascribed to indigestion; but it ceases spontaneously, as the patient acquires the habit of balanc-

ing himself by less distinct objects.

A gentleman about 50 was feized with an uncommon degree of vertigo, fo as to fall on the ground, and not to be able to turn his head, as he fat up either in his chair or in his bed, and this continued eight or ten weeks. As he had many decayed teeth in his mouth, and the vertigo was preceded and fometimes accompanied by pains on one fide of his head, the difease of a tooth was suspected to be the cause. And as his timidity was too great to admit the extraction of those which were decayed; after the trial of cupping repeatedly, fomentations on his head, repeated blifters, with valerian, Peruvian bark, musk, opium, and variety of other medicines; mercurials were used, both externally and internally, with defign to inflame the membranes of the teeth, and by that means to prevent the torpor of the action of the membranes about the temple, and parietal bone; which are catenated with the membranes of the teeth by irritative affociation, but not by fensitive affociation. The event was, that as soon as the gums became fore with a slight ptyalism, the pains about the head and vertigo gradually diminished, and during the foreness of his gums entirely ceased; but I believe recurred

afterwards, though in lefs degree.

The idea of inflaming the membranes of the teeth to produce increased sensation in them, and thus to prevent their irritative connexion with those of the cranium, was taken from the treatment of trismus, or locked jaw, by endeavouring to inflame the injured tendon; which is said to prevent or to remove the spasm of the muscles of the jaw. See Class III. 1. 13. and 15.

M. M. Emetics. Blifters. Iffues about the head. Extraction of decayed teeth. Slight falivation. Sorbentia. Incitantia.

Galvanism.

A lady was fuddenly feized with violent vertigo, so as to prevent her from walking safely across the room, this was attended with considerable diminution of fight; and after various evacuations, and other medicines, had been tried without cure, Mr. Volta's galvanic pillar was used, consisting of about 30 plates of silver, the diameter of about one inch and half, and as many zinc plates, with interposed circles of cloth moistened with brine. A wire connected with each end of this pillar was approached repeatedly to her temples, which were previously moistened with brine, and 100 galvanic shocks were daily passed through the optic nerves, which soon appeared to be of great advantage, and the soon recovered, both from the vertigo and dimness of sight.

12. Vertigo ebriofa. Vertigo from intoxication is owing to the affociation of the irritative ideas of vision with the irritative motions of the stomach. Whence when these latter become much increased by the immoderate stimulus of wine, the irritative motions of the retina are produced with less energy by reverse sympathy, and become at the same time succeeded by sensation in consequence of their decreased action. See Sect. XXI.

3. and XXXV. 1. 2. So conversely when the irritative motions of vision are increased by turning round, or by our unaccustomed agitation at sea, those of the stomach become inverted by reverse sympathy, and are attended in consequence with disagreeable sensation. Which decreased action of the stomach is in consequence of the increased expenditure of the sensorial power on the irritative ideas of vision, as explained in Vertigo rotatoria.

Whence though a certain quantity of vinous spirit stimulates the whole system into increased action, and perhaps even increases the secretion of sensorial power in the brain; yet as soon as any degree of vertigo is produced, it is a proof, that by the too great expenditure of fenforial power by the stomach, and its nearest affociated motions, the more distant ones, as those of vision, become imperfectly exerted. From hence may be deduced the necessity of exhibiting wine in fevers with weak pulse in only appropriated quantity; because if the least intoxication be induced, some part of the system must act more feebly from the unnecessary expenditure of sensorial power.

13. Vertigo febriculofa. Vertigo in fevers either proceeds from the general deficiency of fenforial power belonging to the irritative affociations, or to a greater expenditure of it on fome links of the trains and tribes of affociated irritative motions. There is however a flighter vertigo attending all people, who have been long confined in bed, on their first rising; owing to their having been so long unused to the apparent motions of objects in their erect posture, or as they pass by them, that they have lost in part the habit of balancing themselves by them.

14. Vertigo cerebrofa. Vertigo from injuries of the brain, either from external violence or which attend paralytic attacks, are owing to the general deficiency of fenforial power. In these distressul situations the vital motions, or those immediately necessary to life, claim their share of sensorial power in the first place, otherwise the patient must die; and those motions, which are less necessary, seel a desiciency of it, as these of the organs of sensor and muscles; which constitute vertigo; and lastly the voluntary motions, which are still less immediately necessary to life, are frequently partially destroyed, as in palfy; or

totally, as in apoplexy.

15. Murmur aurium vertiginosum. The vertiginous murmur in the ears, or noise in the head, is compared to the undulations of the found of bells, or to the humming of bees. It frequently attends people about 60 years of age; and like the vifual vertigo described above is owing to our hearing less perfectly from the gradual inirritability of the organ on the approach of age; and the difagreeable fenfation of noise attending it is owing to the less energetic action of these irritative motions; which not being fufficiently diffinct to excite their usual affociations become fucceeded by our attention, like the indistinct view of the apparent motions of objects mentioned in vertigo vifualis. This may be better und food from confidering the use, which blind men make of these irritative founds, which they have taught themselves to attend to, but which escape the notice of others. The late blind Justice Fielding walked for the first time into my room, when he once visited me, and after speaking 2 few words faid, "This room is about 22 feet long, 18

wide, and 12 high;" all which he guessed by the ear with great accuracy. Now if these irritative sounds from the partial loss of hearing do not correspond with the size or usual echoes of the places, where we are; their catenation with other irritative ideas, as those of vision, becomes dissevered or disturbed; and we attend to them in consequence, which I think unravels this intricate circumstance of noises being always heard in the head, when the sense of hearing begins to be impaired, from whatever cause it occurs.

This ringing in the ears also attends the vertigo from intoxication; for the irritative ideas of found are then more weakly excited in confequence of the deficiency of the fenforial power of affociation. As is known by this also being attended with difagreeable fensation, and by its accompanying other diseases of debility, as strokes on the head, fainting fits, and paralytic seizures. For in this vertigo from intoxication fo much fenforial power in general is expended on the increased actions of the stomach, and its nearest connections, as the capillaries of the skin; that there is a deficiency for the purposes of the other irritative affociations of motions usually connected with it. This auditory vertigo attends both the rotatory and the vifual vertigo abovementioned; in the former it is introduced by reverse sympathy, that is, by the diminution of fenforial power; too great a quantity of it being expended on the increased irritative motions of vision; in the latter it is produced either by the same causes which produce the vifual vertigo, or by direct fympathy with its See Sect. XX. 7.

M. M. Stimulate the internal ear by ether, or with effential oil diluted with expressed oil, or with a solution of opium in wine, or in water. Or with salt and water. Apply a cupping glass over the ear. See I. 2. 5. 6. Galvanic shocks through the temples. See IV. 2. 1. 11.

16. Tactus, guflus, olfactus vertiginofs. Vertiginous touch, tafte, and finell. In the vertigo of intoxication, when the patient lies down in bed, it fometimes happens even in the dark, that the bed feems to librate under him, and he is afraid of falling out of it. The fame occurs to people, who are fea-fick, even when they lie down in the dark. In these the irritative motions of the nerves of touch, or irritative tangible ideas, are performed with less energy, in one case by reverse sympathy with the stomach, in the other by reverse sympathy with the nerves of vision, and in consequence become attended with sensation, and produce the fear of falling by other associations.

A vertigo of the fense of touch may be produced, if any one turns round for a time with his eyes shut, and suddenly stops Vol. II.

without opening them; for he will for a time feem to be still going forwards; which is difficult to explain. See Sect. XX. 6.

In the beginning of some fevers, along with incessant vomiting, the patients complain of disagreeable tastes in their mouth, and disagreeable odours; which are to be ascribed to the general debility of the great trains, and tribes of associated and irritative motions, and to be explained from their direct sympathy with the decreased action of a sick stomach; or from the less fecretion of sensorial power in the brain. These organs of sense are constantly stimulated into action by the saliva or by the air; hence, like the sense of hunger, when they are torpid from want of stimulus, or from want of sensorial power, pain or disagreeable sensation ensues, as of hunger, or faintness, or sickness in one case; and the ideas of bad tastes or odours in the other. This accords with the laws of causation, Sect. IV. 5.

17. Pulsus mollis in vomitione. The fostness of the pulse in the act of vomiting is caused by direct affociation between the heart and the stomach; as explained in Sect. XXV. 17. A great slowness of the pulsation of the heart sometimes attends sickness, and even with intermissions of it, as in the exhibition of too great

a dose of digitalis.

18. Pulsus intermittens a ventriculo. When the pulse first begins to intermit, it is common for the patient to bring up a little air from his stomach; which if he accomplishes before the intermission occurs, always prevents it; whence that this debility of the heart is owing to the direct affociation of its motions with those of the stomach is well evinced. See Sect. XXV. 17.

I this morning faw Mr. —, who has long had at times an unequal pulse, with indigestion and statulency, and occasional asthma; he was seized two days ago with diarrhoea, and this morning with sickness, and his pulse was every way unequal. After an emetic his pulse still continued very intermittent and unequal. He then took some breakfast of toast and butter, and tea, and to my great surprise his pulse became immediately perfectly regular, about 100 in a minute, and not weak, by this stimulus on his stomach.

A person, who for many years had had a frequent intermisfion of his pulse, and occasional palpitation of his heart, was relieved from them both for a time by taking about four drops of a faturated solution of arsenic three or four times a day for three or four days. As this intermission of the pulse is occasioned by the direct association of the motions of the heart with those of the stomach, the indication of cure must be to strengthen the action of the stomach by the bark. Spice. Moderate quantities of wine. A blifter. Half a grain of opium twice a day. Solution of arfenic?

19. Febris inirritativa. Inirritative fever described in Class I. 2. 1. 1. belongs to this place, as it confifts of difordered trains and tribes of affociated irritative motions, with leffened actions of the affociated organs. In this fever the pulsations of the heart and arteries are weakened or lessened, not only in the cold paroxysm, as in the irritative fever, but also in the hot paroxysm. The capillary arteries or glands have their actions nevertheless increased after the first cold fit, as appears by the greater production of heat, and the glow of arterial blood in the cutaneous vessels; and lastly, the action of the stomach is much impaired or destroyed, as appears by the total want of appetite to folid food. Whence it would feem, that the torpid motions of the stomach, whatever may occasion them, are a very frequent cause of continued fever with weak pulse; and that these torpid motions of the stomach do not sufficiently excite the fenforial power of affociation, which contributes in health to actuate the heart and arteries along with the irritation produced by the stimulus of the blood; and hence the actions of these organs are weaker. And lastly, that the accumulation the fenforial power of affociation, which ought to be expended on the motions of the heart and arteries, becomes now exerted on the cutaneous and pulmonary capillaries. See Supplement I. 8. and Sect. XXXV. I. I. and XXXIII. 2. 10.

I have dwelt longer on the vertiginous diseases in this genus, both because of their great intricacy, and because they seem to open a road to the knowledge of sever, which consists of affociated trains and tribes of irritative or fensitive motions, which are sometimes mixed with the vertiginous ones, and sometimes sep-

the selection and he was a select that a property of

arate from them.

ORDO II.

Decreased Associate Motions.

GENUS II.

Catenated with Sensitive Motions.

In this genus the fenforial power of affociation is exerted with lefs energy, and thence the actions produced by it are lefs than natural; and pain is produced in confequence, according to the fifth law of animal causation, Sect. IV. This pain is generally attended with coldness of the affected part, and is seldom succeeded by inflammation of it. This decreased action of the fecondary link of the affociated motions, belonging to this genus, is owing to the previous exhaustion of sensorial power either in the increased actions of the primary link of the affociated motions, or by the pain which attends them; both which are frequently the consequence of the stimulus of something external to the affected sibres.

As pain is produced either by excess or defect of the natural exertions of the fibres, it is not, considered separately, a criterion of the presence of either. In the affociations belonging to this genus the sensation of pain or pleasure produces or attends the primary link of the affociated motions, and very often gives

name to the difeafe.

When great pain exists without causing any fibrous motions, I conjecture that it contributes to exhaust or expend the general quantity of sensorial power; because people are fatigued by enduring pain, till at length they sleep. Which is contrary to what I had perhaps erroneously supposed in Sect. XXXV. 2. 3. If it causes fibrous motions, it then takes the name of sensation, according to the definition of sensation in Sect. II. 2. 9.; and increased fibrous action or inflammation is the consequence. This circumstance of the general exhaustion of sensorial power by the existence of pain will assist in explaining many of the diseases of this genus.

Many of the canals of the body, as the urethra, the bile-duct, the throat, have the motions of their two extremities affociated by having been accustomed to feel pleasurable or painful sensations at the same time or in succession. This is termed sensative affociation, though those painful or pleasurable sensations do not cause the motions, but only attend them; and are thus

perhaps, strictly speaking, only catenated with them.

SPECIES.

1. Torpor genæ a dolore dentis. In tooth-ach there is generally a coldness of the cheek, which is sensible to the hand, and is attended in some degree with the pain of cold. The cheek and tooth have frequently been engaged in pleasurable action at the fame time during the masticating of our food; whence they have acquired fensitive associations. The torpor of the cheek may have for its cause the too great expenditure of sensorial power by the painful fensation of the membranes of the difeased tooth; whence the membranes of the cheek affociated with those of the alveolar process are deprived of their natural share of it, and become torpid; thus they produce less secretions, and less heat, and the pain of cold is the consequence. This torpor of the vessels of the cheek cannot be produced by the activity of the fenforial power of fenfation; for then they would act more violently than natural, or become inflamed. And though the pain by exhausting so much sensorial power may be a remote cause, it is the defect of the power of association, which is the immediate cause of the torpor of the cheek.

After some hours this pain occasioned by the torpor of the vessels of the cheek either gradually ceases along with the pain of the diseased tooth; or, by the accumulation of sensorial power during their state of torpor, the capillaries of the cheek act with greater violence, and produce more secretions, and heat, and consequent tumour, and inflammation. In this state the pain of the diseased tooth ceases; as the sensorial power of sensation is now expended on the inflamed vessels of the cheek. It is probable that most other internal membranous inflammations begin in a similar manner; whence there may seem to be a double kind of sensitive association; first, with decreased action of the affociated organ, and then with increased action of it; but the latter is in this case simply the consequence of the former; that is, the tumour or inslammation of the cheek is in consequence of its previous quiescence or torpor.

2. Stranguria a dolore vesica. The strangury, which has its origin from pain at the neck of the bladder, consists of a pain in the external extremity of the urethra or of the glands penis of men, and probably in the external termination of the urethra or of the clitoris of women; and is owing to the sympathy of these with some distant parts, generally with the other end of the urethra; an endeavour and dissiculty of making water attends this pain.

Its remote cause is from the internal or external use of cantharides, which stimulate the neck of the bladder; or from a stone, which whenever it is pushed into the neck of the bladder, gives this pain of strangury, but not at other times; and hence it is felt most severely in this case after having made water.

The fensations or fensitive motions of the glands penis, and of the sphincter of the bladder, have been accustomed to exist together during the discharge of the urine; and hence the two ends of the urethra fympathize by affociation. When there is a stone at the neck of the bladder, which is not so large or rough as to inflame the part, the sphincter of the bladder becomes stimulated into pain; but as the glans penis is for the purposes of copulation more sensitive than the sphincter of the bladder, as foon as it becomes affected with pain by the affociation above mentioned, the fensation at the neck of the bladder ceases; and then the pain of the glans penis would feem to be affociated with the irritative motions only of the sphincter of the bladder, and not with the sensitive ones of it. But a circumstance similar to this occurs in epileptic fits, which at first are induced by difagreeable fenfation, and afterwards feem to occur without previous pain, from the fuddenness with which they follow and relieve the pain, which occasioned them. From this analogy I imagine the pain of the glans penis is affociated with the pain of the sphincter of the bladder; but that as soon as the greater pain in a more sensible part is produced; the less pain, which occasioned it, ceases; and that this is one of the laws of sensitive asfociation. See Sect. XXXV. 2. 1.

A young man had by an accident swallowed a large spoonful or more of tincture of cantharides; as soon as he began to seel the pain of strangury, he was advised to drink large quantities of warmish water: to which, as soon as it could be gotten, some gum arabic was added. In an hour or two he drank by intervals of a few minutes about two gallons of water, and discharged his urine every four or sive minutes. A little blood was you'ded towards the end, but he suffered no ill consequence.

M. M. Warm water internally. Clyfters of warm water. Fomentation. Opium. Solution of fixed alkali fuperfaturated with carbonic acid. A bougie may be used to push back a stone

into the bladder. See Class I. 1. 3. 10.

3. Stranguria convulsiva. The convulsive strangury, like that before described, is probably occasioned by the torpor or desective action of the painful part in consequence of the too great expenditure of sensorial power on the primary link of the associated motions, as no heat or inflammation attends this violent pain. This kind of strangury recurs by stated periods, and sometimes arises to so great a degree, that convulsion or temporary madness terminates each period of it. It affects women oftener

than men, is attended with cold extremities without fever, and is diftinguished from the stone of the bladder by the regularity of its periods, and by the pain being not increased after making water.

On introducing the cathether fometimes part of the urine will come away and not the whole, which is difficult to explain; but may arise from the weakness of the muscular fibres of the bladder; which are not liable suddenly to contract themselves so far as to exclude the whole of the urine. In some old people, who have experienced a long retention of urine, the bladder never regains the power of completely emptying itself; and many who are beginning to be weak from age can make water a second time, a sew minutes after they supposed they had emptied the bladder.

I have believed this pain to originate from fympathy with fome distant part, as from ascarides in the rectum, or from piles in women; or from caruncles in the urethra about the caput gallinaginis in men; and that the pain has been in the glans or clitoris by reverse sympathy of these more sensible parts with those above mentioned.

M. M. Venesection. Opium in large quantities. Warm bath. Balsams. Bark. Tincture of cantharides. Bougie, and the treatment for hæmorrhoids. Leeches applied to the sphicter ani. Aerated alkaline water. Soap and sal soda. Opium in clysters given an hour before the expected return. Smoke of tobacco in clysters. Arsenic.

4. Dolor termini intestinalis ductus choledochi. Pain at the intestinal end of the gall-duct. When a gall-stone is protruded from the gall-bladder a little way into the end of the gall-duct, the pain is felt at the other end of the gall-duct, which terminates in the duodenum. For the actions of the two terminations of this canal are affociated together from the fame streams of bile passing through them in succession, exactly as the two terminations of the urethra have their actions affociated, as described in Species 2 and 3 of this genus. But as the intestinal termination of the bile-duct is made more sensible for the purpose of bringing down more bile, when it is stimulated by new supplies of food from the stomach, it falls into violent pain from affociation; and then the pain on the region of the gall-bladder ceases, exactly as above explained in the account of the pain of the glans penis from a stone in the sphincter of the bladder.

The common bile-duct opens into the intestine exactly at what is called the pit of the stomach; and hence it has sometimes happened, that this pain from association with the sensa-

tion of a gall-stone at the other end of the bile-duct has been

mistaken for a pain of the stomach.

For the method of cure fee Class I. 1. 2. 8. to which should be added the use of strong electric shocks passed through the bileduct from the pit of the stomach to the back, and from one fide to the other. A case of the good effect of electricity in the jaundice is related in Sect. XXX. 2. And another case, where it promoted the passage of a painful gall-stone, is described by Dr. Hall, experienced on himself. Trans. of the College at Philadelphia, Vol. I p. 192.

Half a pint of warm water two or three times a day is much

recommended to dirute the inspissated bile.

5. Dolor pharyngis ab acido gastrico. The two ends of the throat sympathize by sensitive association in the same manner as the other canals above mentioned, namely, the urethra and the bile-duct; hence when too great acidity of undigested aliment, or the carbonic acid air, which escapes in fermentation, stimulates the cardia ventriculi, or lower end of the gula, into pain, the pharynx, or upper end of it, is affected with greater

pain, or a difagreeable fensation of heat.

6. Pruritus narium a vermibus. The itching of the nose from worms in the intestines is another curious instance of the senfitive affociations of the motions of membranes; especially of those which constitute the canals of the body. Previous to the deglutition of agreeable food, as milk in our earliest infancy, an agreeable odour affects the membrane, which lines the nostrils; and hence an affociation feems to take place between the agreeable fenfations produced by food in the stomach and bowels, and the agreeable fensations of the nostrils. The existence of ascarides in the rectum I believe produces this itching of the nostrils more than the worms in other parts of the intestines; as we have already feen, that the terminations of canals sympathize more than their other parts, as in the urethra and gall-ducts. See Clafs I. 4. 5. 9. IV. 1. 2. 9.

7. Cephalea sympathetica. Sympathetic head-ach. In cold fits of the ague, the head-ach arises from consent with some torpid viscus, like the pain of the loins. After drunkenness the headach is very common, owing to direct sympathy of the membranes of the head with those of the stomach; which is become torpid after the too violent ftimulus of the preceding intoxication; and is hence removable by spirit of wine, or opium, exhibited in fmaller quantities. In some constitutions these headachs are induced, when the feet are exposed to much external cold; in this case the feet should be covered with oiled silk, which prevents the evaporation of the perspirable matter, and thence diminishes one cause of external cold.

M. M. Valerian in powder two drams three or four times a day is recommended. The bark. Chalybeates. A grain of opium twice a day for a long time. From five to ten drops of the faturated folution of arsenic two or three times a day. See Class I. 2. 4. 11. A lady once affured me, that when her headach was coming on, she drank three pints (pounds) of hot water, as hastily as she could; which prevented the progress of the difease. A solution of arsenic is recommended by Dr. Fowler of York. Very strong errhines are faid sometimes to cure headachs taken at the times the pain recurs, till a few drops of blood iffue from the nostrils. As one grain of tupeth mineral (vitriolic calx of mercury) mixed with ten grains of fine fugar. Euphorbium or cayenne pepper mixed with fugar, and used with caution as an errhine. See the M. M. of the next Species.

8. Hemicrania sympathetica. Sympathetic pain on one side of the head. This disease is attended with cold skin, and hence whatever may be the remote cause, the immediate one seems to be want of stimulus, either of heat or distention, or of some other unknown stimulus in the painful part; or in those, with which it is affociated. The membranes in their natural state are only irritable by diftention; in their diseased state, they are fensible like muscular fibres. Hence a diseased tooth may render the neighbouring membranes fensible, and is frequently the

cause of this disease.

Sometimes the stomach is torpid along with the pained membrane of the head; and then fickness and inappetency attend either as causes or consequences. The natural cure of hemicrania is the accumulation of fenforial power during the rest or fickness of the patient. Mrs. - is frequently liable to hemicrania with fickness, which is probably owing to a diseased tooth; the paroxyfm occurs irregularly, but always after fome previous fatigue, or other cause of debility. She lies in bed, fick, and without taking any folid food, and very little of fluids, and those of the aqueous kind, and, after about 48 or 50 hours, rises free from complaint. Similar to this is the recovery from cold paroxysms of fever, from the torpor occasioned by fear, and from fyncope; which are all owing to the accumulation of fenforial power during the inactivity of the system. Hence it appears, that, though when the fenforial power of volition is much exhausted by fatigue, it can be restored by eight or ten hours of fleep; yet, when the sensorial power of irritation is exhausted by fatigue, that it requires two whole folar or lunar days of reft, before it can be restored.

The late Dr. Monro afferted in his lectures, that he cured the hemicrania, or megrim, by a strong vomit, and a brisk purge immediately after it. This method succeeds best if opium and the bark are given in due quantity after the operation of the cathartic; and with still more certainty, if bleeding in small quantity is premised, where the pulse will admit of it. See Sect. XXXV. 2.11.

Mr. Keilie afferts, that fome kinds of head-achs, especially those which arise from defect of stimulation, may be cured by compressing the two subclavian arteries, as they pass over the first rib; which he thinks would produce a pressure on the brain similar to that, which may be produced by the centrifugal force, if a person was to lie across a mill-stone as it revolves. See Suppl. I. 15. 7. Would such a circulating bed remove any kind of head-ach?

The pain generally affects one eye, and spreads a ltitle way on that fide of the nose, and may sometimes be relieved by pressing or cutting the nerve, where it passes into the bone of the orbit above the eye. When it affects a small defined part on the parietal bone on one fide, it is generally termed Clavus hyftericus, and is always I believe owing to a difeafed dens molaris. The tendons of the muscles, which serve the office of mastication, have been extended into pain at the same time that the membranous coverings of the roots of the teeth have been compressed into pain, during the biting or mastication of hard bodies. Hence when the membranes, which cover the roots of the teeth, become affected with pain by a beginning decay, or perhaps by the torpor or coldness of the dying part of the tooth, the tendons and membranous fascia of the muscles about the fame fide of the head become affected with violent pain by their fensitive affociations: and as foon as this affociated pain takes place, the pain of the tooth entirely ceases, as explained in the fecond species of this genus.

A remarkable circumstance attends this kind of hemicrania, viz. that it recurs by periods like those of intermittent fevers, as explained in the Section on Catenation of Motions; these periods sometimes correspond with alternate lunar or solar days like tertian agues, and that even when a decaying tooth is evidently the cause; which has been evinced by the cure of the disease by extracting the tooth. At other times they observe the monthly lunations, and seem to be induced by the debility, which attends menstruation.

The dens fapientiæ, or last tooth of the upper jaw, frequently decays first, and gives hemicrania over the eye on the same side. The first or second grinder in the under-jaw is lia-

ble to give violent pain about the middle of the parietal bone, or fide of the head, on the fame fide, which is generally called the Clavus hystericus, of which an instructive case is related in Sect. XXXV. 2. 1.

Since the above was first published I have seen two cases, which were very fimilar, and feem much to confirm the above theory of sympathetic hemicrania being perhaps always owing to the sympathy of the membranes about the cranium with those about diseased teeth. Lord M. and Mr. B. of Edinburgh, both of them about the middle of life were afflicted with violent hemicrania for about two years; in the beginning of which time they both affured me, that their teeth were perfectly found, but on inspecting their mouths I found all the molares were now fo decayed as to have lost their crowns. After having suffered pain for fixteen or eighteen months almost incessantly in different parts of their heads, they had each of them a hemiplegia, from which they gradually recovered, as much as paralytic affections generally do recover. All the stumps of their teeth, which were useless, were directed to be extracted; as the swallowing fo much putrid matter from decaying bones feemed to injure their digestion. They were defired not to drink wine or ale without its being diluted with twice or thrice its quantity of water, to prevent any access of torpor from too great previous stimulus, and to take fix grains of rhubarb with three of soap made into pills, every night, with some bitter and very slight chalybeate medicines. If the teeth which became torpid in fuccession, could have been discovered, and extracted, before they decayed, and could have been replaced, might not this continuance of pain, and confequent paralysis, have been prevented? or might not a moderate fallivation have effected this purpose?

M. M. Detect and extract the diseased tooth. Cut the affected nerve, or stimulate the diseased membrane by acupuncture. Venesection to six ounces by the lancet or by leeches. A strong emetic and a subsequent cathartic; and then an opiate and the bark. Pass small electric shocks through the pained membrane, and through the teeth on the same side. Apply vitriolic ether externally, and a grain of opium with camphor internally, to the cheek on the affected side, where a diseased tooth may be suspected. Foment the head with warm vinegar. Drink two large spoonfuls of vinegar. Stimulate the gums of the suspected teeth by oil of cloves, by opium. See Class I. 1. 4. Snuff volatile spirit of vinegar up the nostrils. Lastly, in permanent head-achs, as in permanent vertigo, I have seen good effect in two cases by the use of mercurial ointment rubbed on the shaved head or about the throat, till a mild salivation com-

mences, which by inflaming the membranes of the teeth may prevent their irritative fympathy with those of the cranium. Thus by inflaming the tendon, which is the cause of locked jaw, and probably by inflaming the wound, which is the cause of hydrophobia, those diseases may be cured, by disuniting the irritative fympathy between those parts, which may not possess any fensitive fympathy. This idea is well worth our attention.

Otalgia. Ear-ach is another disease occasioned by the sympathy of the membranes of the ear with those which invest or surround a decaying tooth, as I have had frequent reason to believe; and is frequently relieved by filling the ear with tincture.

of opium. See Class I. 2. 4.

9. Dolor humeri in hepatidide. In the efforts of excluding the fæces and urine the muscles of the shoulders are exerted to compress the air in the lungs, that the diaphragm may be pressed down. Hence the distention of the tendons or fibres of these muscles is affociated with the distention of the tendons or fibres of the diaphragm; and when the latter are pained by the enlargement or heat of the inslamed liver, the former sympathize with them. Sometimes but one shoulder is affected, sometimes both; it is probable that many other pains, which are termed rheumatic, have a similar origin, viz. from sensitive associations.

As no inflammation is produced in confequence of this pain of the shoulder, it seems to be owing to inaction of the membranous part from defect of the sensorial power of association, of which the primary link is the inflamed membrane of the liver; which now expends so much of the sensorial power in general by its increased action, that the membranes about the shoulder, which are links of association with it, become deprived of their usual share, and consequently fall into torpor.

nent of the eruption of the small-pox, when the face and breast of children are very hot, their extremities are frequently cold. This I ascribe to sensitive affociation between the different parts of the skin; whence when a part acts too violently, the other part is liable to act too weakly; and the skin of the face being affected first in the eruption of the small-pox, the skin of the

feet becomes cold in confequence by reverse sympathy.

M. M. Cover the feet with flannel, and expose the face and bosom to cool air, which in a very short time both warms the feet and cools the face; and hence what is erroneously called a rash, but which is probably a too hasty eruption of the small-pox, disappears; and afterwards fewer and more distinct eruptions of the small-pox supervene.

11. Testium

11. Testium dolor nephriticus. The pain and retraction of the tefficle on the same side, when there is a stone in the ureter, is to be afcribed to fenfitive affociation; whether the connecting cause be a branch of the same nerve, or from membranes, which have been frequently affected at the fame time.

12. Dolor digiti minimi sympatheticus. When any one accidentally strikes his elbow against any hard body, a tingling pain runs down to the little finger end. This is owing to fensitive affociation of motions by means of the same branch of a nerve, as in hemicrania from a decaying tooth the pain is owing to the fensitive affociation of tendons or membranes.

13. Dolor brachii in hydrope pectoris. The pain in the left arm which attends some dropsies of the cheft, is explained in Sect. XXIX. 5. 2. 10. which refembles the pain of the little finger from a percussion of the nerve at the elbow in the preceding article. A numbness of this kind is produced over the whole leg, when the crural nerve is much compressed by sitting for a time

with one leg croffed over the other.

Mr. ——, about fixty, had for two years been affected with difficulty of respiration on any exertion, with pain about the sternum, and of his left arm; which last was more considerable than is usual in dropfy of the chest; some months ago the pain of his arm, after walking a mile or two, became excessive, with coldness and numbness; and on the next day the back of the hand, and a part of the arm swelled and became inflamed, which relieved the pain; and was taken for the gout, and continued feveral days. He after fome months became dropfical both in respect to his chest and limbs, and was fix or seven times perfeetly relieved by one dram of saturated tincture of digitalis, taken two or three times a day for a few days in a glass of peppermint water. He afterwards breathed oxygen gas undiluted, in the quantity of fix or eight gallons a day for three or four weeks without any effect, and funk at length from general debility.

In this instructive case I imagine the pressure or stimulus of one part of the nerve within the cheft caused the other part, which serves the arm, to become torpid, and consequently cold by fympathy; and that the inflammation was the confequence of the previous torpor and coldness of the arm, in the same manner as the swelling and inflammation of the cheek in toothach, in the first species of this genus; and that many rheumatic inflammations are thus produced by fympathy with some dif-

14. Diarrhæa a dentitione. The diarrhæa, which frequently attends dentition, is the confequence of indigestion; the aliment acquires acquires chemical changes, and by its acidity acts as a cathartic; and changes the yellow bile into green, which is evacuated along with indigested parts of the coagulum of milk. The indigestion is owing to the torpor of the stomach and intestines caused by their affociation with the membranes of the gums, which are now stimulated into great exertion with pain; both which contribute to expend the general quantity of sensorial power, which belongs to this membranous affociation; and thus the stomach and intestines act with less than their natural energy. This is generally esteemed a favourable symptom in difficult dentition, as the pain of the alveolar membranes exhausts the sensorial power without producing convulsions for its relief. See Class I. 1. 4. 5. And the diarrhæa ceases, as the tooth advances.

ORDO II.

Decreased Associate Motions:

GENUS III.

Catenated with Voluntary Motions.

SPECIES.

1. Titubatio lingue. Impediment of speech is owing to the affociations of the motions of the organs of speech being interrupted or dissevered by ill-employed sensation or sensitive motions, as by awe, bashfulness, ambition of shining, or fear of not succeeding, and the person uses voluntary efforts in vain to regain the broken affociations, as explained in Sect. XVII. 1. 10. and XVII. 2. 10.

The broken affociation is generally between the first confonant and the succeeding vowel; as in endeavouring to pronounce the word parable, the p is voluntarily repeated again and again, but the remainder of the word does not follow, because the afsociation between it and the next vowel is different.

M. M. The art of curing this defect is to cause the stammerer to repeat the word, which he finds difficult to speak, eight or ten times without the initial letter, in a strong voice, or with an aspirate before it, as arable, or harable; and at length to speak it very softly with the initial letter p, parable. This should be practised for weeks or months upon every word, which the stammerer hesitates in pronouncing. To this should be added much commerce with mankind, in order to acquire

a carelessness about the opinions of others.

2. Chorea Sti Viti. In the St. Vitus's dance the patient can at any time lie still in bed, which shews the motions not to be convulsive; and he can at different times voluntarily exert every muscle of his body; which evinces, that they are not paralytic. In this disease the principal muscle in any designed motion obeys the will; but those muscles, whose motions were associated with the principal one, do not act; as their association is dissevered, and thus the arm or leg is drawn outward, or inward, or backward, instead of upward or forward, with various gesticulations exactly resembling the impediment of speech.

This difease is frequently left after the itch has been too hashily cured. See convulsio dolorifica, Class III. 1. 1. 6. A girl about eighteen, after wearing a mercurial girdle to cure the itch,

acquired

acquired the Chorea St. Viti in so universal a manner, that her speech became affected as well as her limbs; and there was evidently a distunion of the common trains of ideas; as the itch was still among the younger children of the family, she was advised to take her sister as a bedsellow, and thus received the itch again; and the dance of St. Vitus gradually ceased. See Class II. 1. 5. 6.

M. M. Give the patient the itch again. Calomel a grain every night, or fublimate a quarter of a grain twice a day for a fortnight. Steel. Bark. Warm bath. Cold bath. Opium. Venelection once at the beginning of the difease. Electricity. Perpetual flow and repeated efforts to move each limb in the designed direction, as in the titubatio linguæ above described.

3. Rifus. Laughter is a perpetual interruption of voluntary exertion by the interpolition of pleasurable sensation; which not being checked by any important consequences rises into pain, and requires to be relieved or moderated by the frequent repetition of voluntary exertion. See Sect. XXXIV. 1 4. and

Class III. 1. 1. 4. and IV. 1. 3. 3.

4. Tremor ex irâ. The trembling of the limbs from anger. The interruption of the voluntary affociations of motions by anger, originates from too great a part of the fenforial power being exerted on the organs of fenfe; whence the muscles, which ought to support the body upright, are deprived of their due quantity,

and tremble from debility. See Class III. 2. 1. 1.

5. Rubor ex irâ. Redness from anger. Anger is an excess of aversion, that is of voluntarity not yet employed. It is excited by the pain of offended pride; when it is employed it becomes outrage, cruelty, infanity. The cutaneous capillaries, especially those of the face, are more mobile, that is, more easily excited into increased action, or more easily become torpid, from less variation of sensorial power, than any other parts of the fystem, which is owing to their being perpetually subject to the viciflitudes of heat and cold, and of extension and corrugation. Hence, when an excess of voluntarity exists without being immediately expended in the actions of the large muscles, the capillary arteries and glands acquire more energetic action, and a flushed skin is produced, with increased secretion of perspirable matter, and consequent heat, owing to the pause or interruption of voluntary action; and thus the actions of these cutaneous vessels become affociated between the irascent ideas and irascent muscular actions, which are thus for a time interrupted.

6. Rubor criminati. The blushing of accused people, whether guilty or not, appears to be owing to circumstances similar to

that of anger; for in these situations there is always a suddent voluntarity, or wish, of clearing their characters arises in the mind of the accused person; which, before an opportunity is given for it to be expended on the large muscles, influences the capillary arteries and glands, as in the preceding article. Whence the increased actions of the capillaries, and the consequent redness and heat, become exerted between the voluntary ideas of self-defence, and the muscular actions necessary for that purpose; which last are thus for a time interrupted or delayed.

Even in the blush of modesty or bashfulness there is a selfcondemnation for some supposed defect or indecorum, and a sudden voluntarity, or wish, of self-defence; which not being expended in actions of the larger muscles excites the capillaries into action; which in these subjects are more mobile than in

others.

The blush of young girls on coming into an affembly room, where they expect their dress, and steps, and manner, to be examined, as in dancing a minuet, may have another origin; and may be considered as a hot sit of returning considerce, after a

previous cold fit of fear.

7. Tarditas paralytica. By a stroke of the palfy or apoplexy it frequently happens, that those ideas which were affociated in trains, whose first link was a voluntary idea, have their connection differenced; and the patient is under the necessity, by repeated efforts, flowly to renew their affociations. In this fituation those words, which have the fewest other words affociated with them. as the proper names of persons or places, are the most difficult to recollect. And in those efforts of recollection the word opposite to the word required is often produced, as hot for cold, winter for fummer, which is owing to our affociating our ideas of things by their opposites as well as by their similitudes, and in some instances perhaps more frequently, or more forcibly. Other paralytic patients are liable to give wrong names to external objects, as using the word pigs for sheep, or cows for horses; in this case the affociation between the idea of the animal and the name of it is differered; but the idea of the class or genus of the thing remains; and he takes a name from the first species which presents itself, and sometimes can correct himself, till he finds the true one.

8. Tarditas senilis. Slowness of age. The difficulty of associating ideas increases with our age; as may be observed from old people forgetting the business of the last hour, unless they impress it strongly, or by frequent repetition, though they can well recollect the transactions of their youth. I saw an elderly man, who could reason with great clearness and precision, and

Vol. II. Ggg in

in accurate language on subjects, which he had been accustomed to think upon; and yet did not know that he had rung the bell by his fire-side in one minute afterwards; nor could then recollect the object he had wanted, when his fervant came.

Similar to this is the difficulty which old people experience in learning new bodily movements, that is, in affociating new mufcular actions, as in learning a new trade or manufacture. The trains of movements, which obey volition, are the last which we

acquire; and the first, which are diffociated.

The fymbols most in use, with which we have affociated ideas, are those of visible and of audible language. It is curious to observe in the instruction of young people, that some remember written language the best, and others vocal language. The same thing sometimes occurs in aged people, that is, that some lose the ideas affociated with sounds soonest, and others those affociated with letters. See recollectionis jactura, Class III. 2. 2. 1. and Tarditas paralytica above.

The following curious account of this defect of affociation of ideas with audible but not with visible fymbols was fent me by

Dr. Darwin of Shrewsbury.

"The case of an old man lately occurred to me, who was superanuated; his hearing and vision were perfect, but he could only call up a train of ideas from the latter. When he was told it was nine o'clock, and time for him to eat his breakfast, he repeated the words distinctly but without understanding them. His servant put a watch into his hand. "Why, William, have not I my breakfast, for it is just nine o'clock?" he would say with expression, that shewed he felt what he said.

"On almost every occasion his servants conversed with him by visible objects, although his hearing was perfect; and when this kind of communication was used, he did not appear impaired in his intellects. This state came on from a stroke of the palfy; and till he and his attendants used this kind of language

he was quite childish."

ORDO II.

Decreased Associate Motions.

GENUS IV.

Catenated with External Influences.

As the diseases, which obey sol r or lunar periods, commence with torpor or inactivity, such as the cold paroxysms of severs, the torpor and consequent pain of hemicrania, and the pains which precede the fits of epilepsy and convulsion, it would seem, that these diseases are more generally owing to the diminution than to the excess of solar or lunar gravitation; as the diseases which originate from the influence of the matter of heat, are much more generally in this country produced by the desect

than by the excess of that fluid.

The periodic returns of fo many diseases coincide with the diurnal, monthly, and annual rounds of time; that any one, who would deny the influence of the sun and moon on the periods of quotidian, tertian, and quartan severs, must deny their effect on the tides, and on the seasons. It has generally been believed, that solar and lunar effect was exerted on the blood; which was thus rendered more or less stimulant to the system, as described in Sect. XXXII. 6. But as the sluid matter of gravitation permeates and covers all things, like the sluid matter of heat; I am induced to believe, that gravitation acts in its medium state rather as a causa sine quâ non of animal motion like heat; which may disorder the system chemically or mechanically, when it is diminished; but may nevertheless stimulate it, when increased, into animal exertion.

Without heat and motion, which some philosophers still believe to be the same thing, as they so perpetually appear together, the particles of matter would attract and move towards each other, and the whole universe freeze or coalesce into one solid mass. These therefore counteract the gravitation of bodies to one centre; and not only prevent the planets from falling into the sun, but become either the efficient causes of vegetable and animal life, or the causes without which life cannot exist; as by their means the component particles of matter are enabled to slide over each other with all the various degrees of sluidity and repul-

fion.

As the attraction of the moon countervails or diminishes the terrene gravitation of bodies on the surface of the earth; a tide

rifes on that fide of the earth, which is turned towards the moon: and follows it, as the earth revolves. Another tide is raifed at the same time on the opposite side of the revolving earth, which is owing to the greater centrifugal motion of that fide of the earth, which counteracts the gravitation of bodies near its furface. For the earth and moon may be confidered as two cannon balls of different fizes held together by a chain, and revolving once a month round a common centre of gravity between them, near the earth's furface; at the fame time that they perform their annual orbits round the fun. Whence the centrifugal force of that fide of the earth, which is farthest from this centre of motion, round which the earth and moon monthly revolve, is confiderably greater, than the centrifugal force of that fide of the earth which is nearest it; to which should be added, that this centrifugal force not only contributes to diminish the terrene gravitation of bodies on the earth's furface on that fide furthest from the centre of motion, but also to increase it on that side, which is nearest it.

Another circumstance, which tends to raise the tide on the part of the earth's surface, which is most distant from the moon, is, that the attraction of the moon is less on that part of the ocean, than it is on the other parts of the earth. Thus the moon may be supposed to attract the water on the side of the earth nearest it with a power equal to three; and to attract the central parts of the earth with a power equal to two; and the water on the part of the earth most distant from the moon with a power only equal to one. Hence on the side of the earth most distant from the moon, the moon's attraction is less, and the centrifugal force round their common centre of motion is greater; both which contribute to raise the tides on that side of the earth. On the side of the earth nearest the moon, the moon's attraction is so much greater as to raise the tides; though the centrifugal force of the surface of the earth round their common centre of mo-

tion in some degree opposes this effect.

On these accounts, when the moon is in the zenith or nadir, the gravitation of bodies on the earth's surface will be greatest at the two opposite quadratures; that is, the greatest gravitation of bodies on the earth's surface towards her centre during the lunar day is about six hours and a half after the southing, or after the northing of the moon.

Circumstances similar to these, but in a less degree, must occur in respect to the solar influence on terrestrial bodies; that is, there must be a diminution of the gravity of bodies near the earth's surface at noon, when the sun is over them; and also at midnight from the greater centrifugal force of that side of

the earth, which is most distant from the centre, round which the earth moves in her annual orbit, than on the side nearest that centre. Whence it likewise follows, that the gravitation of bodies towards the earth is greatest about six hours after noon, and after midnight.

Now when the sun and moon have their united gravitation on the same side of the earth, as at the new moon; or when the solar attraction coincides with the greater centrifugal motion of that side of the earth, which is surthest distant from the moon, as at the sull moon; and when this happens about noon or midnight, the gravitation of terrene bodies towards the earth will be greater about six hours after noon, and after midnight, than at any other part of the lunar period; because the attraction of both these luminaries is then exerted on those sides of the earth over which they hang, which at other times of the month are more or less exerted on other parts of it.

Lastly, as heat and motion counteract the gravitation of the particles of bodies to each other, and hence become either the efficient causes of vegetable and animal life, or the causes without which life cannot exist, it seems to follow, that when our gravitation towards the earth's centre is greatest, the powers of life should be the least; and hence that those diseases, which begin with torpor, should occur about six hours after the solar or lunar moon, or about six hours after the solar or lunar midnight; and this most frequently about six hours after or before the new or full moon; and especially when these happen at noon or at midnight; or lastly, according to the combination of these powers in diminishing or increasing the earth's attraction to bodies on its surface.

The returns or exacerbations of many fevers, both irritative and inflammatory, about fix in the evening, and of the periodic cough described in Sect. XXXVI. 3. 9. countenance this theory. Tables might be made out to shew the combined powers of the sun and moon in diminishing the gravitation of bodies on the earth's surface, at every part of their diurnal, monthly, and annual periods; and which might facilitate the elucidation of this subject. But I am well aware of the difficulty of its application to diseases, and hope these conjectures may induce others to publish more numerous observations, and more conclusive reasonings.

SPECIES.

1. Somni periodus. The periods of sleeping and of waking are shortened or prolonged by so many other circumstances in animal life, besides the minute difference between diurnal and

nocturnal folar gravitation, that it can fearcely be afcribed to this influence. At the fame time it is curious to observe, that vegetables in respect to their times of sleeping more regularly observe the hour of the day, than the presence or absence of light, or of heat, as may be seen by consulting the calendar of Flora. Bo-

tanic Garden, Part II. Canto 2. l. 165. note.

Some diseases, which at first light might be supposed to be influenced by solar periods, seem to be induced by the increasing sensibility of the system to pain during our sleeping hours; as explained in Sect. XVIII. 15. Of these are the fits of asthma, of some epilepsies, and of some hemoptoes; all which disturb the patient after some hours sleep, and are therefore to be ascribed to the increase of our dormant sensibility. There may likewise be some doubt, whether the commencement of the pain of gout in the soot, as it generally makes its attack after sleep, should be ascribed to the increased sensibility in sleep, or to solar influence?

M. M. When afthmatic or epileptic fits or hæmoptoe occur after a certain number of hours of fleep, the patient should be forcibly awakened before the expected time by an alarm clock, and drink a cup of chocolate or lemonade.—Or a grain of opium should be given at going to bed.—In one case to prevent the too great increase of sensibility by shortening the time of sleep; and in the other by increasing the irritative motions, and

expending by that means a part of the fenforial power.

2. Studii inanis periodus. Class III. 1. 2. 2. The cataleptic spassin which preceded the reverie and somnambulation in the patient, whose case is related in Sect. XIX. 2. occurred at exactly the same hour, which was about eleven in the morning for many weeks; till those periods were disturbed by large doses of opium; and must therefore be referred to some effect of solar gravitation. In the ease of Master A. Sect. XXXIV. 3. as the reverie began early in the morning during sleep, there may be a doubt, whether this commenced with torpor of some organ catenated with solar gravitation; or was caused by the existence of a previous torpid part, which only became so painful as to excite the exertions of reverie by the perpetual increase of sensibility during the continuance of sleep, as in some fits of epilepsy, as and haemoptoe mentioned in the preceding article.

3. Hemicrania periodus. Periods of Hemicrania. Class IV.
2. 2. 8. The torpor and confequent pain of some membranes on one side of the head, as over one eye, are frequently occapioned by a decaying tooth, and are liable to return every day, or on alternate days at solar or lunar periods. In this case large quantities of the bark will frequently cure the disease, and es-

pecially if preceded by venefection and a brifk cathartic; but if the offending tooth can be detected, the most certain cure is its extraction. These partial head-achs are also liable to return at the greater lunar periods, as about once month. Five drops from a two-ounce phial of a faturated solution of arsenic twice a day for a week or two have been said to prevent the returns of this disease. See a Treatise on Arsenic by Dr. Fowler, of York.

Strong errhines have also been recommended.

4. Epilepsia description periodus. Class III. 1. 1. 8. The pain which induces after about an hour the violent convulsions or infanity, which constitute the painful epilepsy, generally observe solar diurnal periods for four or five weeks, and are probably governed by solar and lunar times in respect to their greater periods; for I have observed that the daily paroxysms, unless disturbed by large doses of opium, recur at very nearly the same hour, and after a few weeks the patients have recovered to relapse again at the interval of a few months. But more observations are wanted upon this subject, which might be of great advantage in preventing the attacks of this disease; as much less opium given an hour before its expected daily return will prevent the paroxysm, than is necessary to cure it, after it has commenced.

5. Convulsionis dolorifica periodus. Class III. 1. 1. 6: The pains, which produce these convulsions, are generally left after-rheumatism, and come on when the patients are become warm in bed, or have been for a short time asseep, and are therefore perhaps rather to be ascribed to the increasing sensibility of the system during sleep, than to solar diurnal periods, as in Species

first and second of this Genus.

6. Tuffis periodica periodus. Periodic cough, Class IV. 2. 1. 9. returns at exact folar periods; that described in Sect. XXXVI. 3. 9. recurred about seven in the afternoon for several weeks, till its periods were disturbed by opium, and then it recurred at eleven at night for about a week, and was then totally destroyed by opium given in very large quantities, after having been

previously for a few days omitted.

7. Catamenia periodus. Periods of menstruation. The correspondence of the periods of the catamenia with those of the moon was treated of in Sech XXXII. 6. and can admit of no more doubt, than that the returns of the tides are governed by lunar influence. But the manner in which this is produced, is less evident; it has commonly been ascribed to some effect of the lunar gravitation on the circulating blood, as mentioned in Sect. XXXII. 6. But it is more analogous to other animal phenomena to suppose that the lunar gravitation immediately

affects the folids by its influx or stimulus. Which we believe of the fluid element of heat, in which we are equally immersed; and of the electric fluid, which also surrounds and pervades us.

See Sect. XXXVI. 2. 3.

If the torpor of the uterine veins, which induces the monthly periods of the catamenia, be governed by the increase of terrene gravitation; that is, by the deficiency of the counter-influence of folar and lunar gravitation; why does not it occur most frequently when the terrene gravitation is the greatest, as about fix hours after the new moon, and next to that at about fix hours after the full moon? This question has its difficulty; first, if the terrene gravitation be greatest about fix hours after the new moon, it must become less and less about the same time every lunar day, till the end of the first quarter, when it will be the least; it must then increase daily till the full. After the full the terrene gravitation must again decrease till the end of the third quarter, when it will, again be the leaft, and must increase again till the new moon; that is, the folar and lunar counter-gravitation is greatest, when those luminaries are vertical, at the new moon, and full moon, and least about six hours afterwards. If it was known, whether more menstruations occur about six hours after the moon is in the zenith or nadir; and in the second and sourth quarters of the moon, than in the first and third; some light would be thrown on this subject; which must in that respect wait for future observations.

Secondly, if the lunar influence produces a very small degree of quiescence, suppose of the uterine veins, at first; and if that recurs at certain periods, as of lunar days, or about 25 hours, even with less power to produce quiescence than at first; yet the quiescence will daily increase by the acquired habit acting at the same time, as explained in Sect. XII. 3. 3. till at length so great a degree of quiescence will be induced as to cause the inaction of the veins of the uterus, and consequent venous hæmorrhage. See Sect. XXXII. 6. Class I. 2. 1. 11. IV. 1. 4. 4. See the introduction to this Genus.

8. Hemorrhoidis periodus. The periods of the piles depend on the torpor of the veins of the rectum, and are believed to recur nearly at monthly intervals. See Sect. XXVII. 2. and

Class I: 2. 1. 6.

9. Podagra periodus. The periods of gout in some patients recur at annual intervals, as in the case related above in Class IV. 1. 2. 15. in which the gouty paroxysm returned for three successive years on nearly the same day of the month. The commencement of the pain of each paroxysm is generally a few hours after midnight, and may thence either be induced by di-

urnal folar periods, or by the increasing fensibility during sleep,

as mentioned in the first species of this genus.

10. Eryspelatis periodus. Some kinds of eryspelas which probably originate from the association of the cutaneous vessels with a diseased liver, occur at monthly periods, like the hæmorrhois or piles; and others at annual periods, like the gout; as a torpor of some part I suppose always precedes the eryspelatous inflammation, the periods should accord with the increasing influence of terrene gravitation, as described in the introduction to this Genus, and in species the seventh of it. Other periods of diseases referable to solar and lunar influence are mentioned in Section XXXVI. and many others will probably be discovered by future observation.

ment of the cold fits of intermittent fevers, and the daily exacerbations of other fevers, fo regularly recur at diurnal folar or lunar periods, that it is impossible to deny their connection with gravitation; as explained in Sect. XXXVI. 3. Not only these exacerbations of fever, and their remissions, and the diurnal solar and lunar periods; but the preparatory circumstances, which introduce fevers, or which determine their crisses, appear to be governed by the parts of monthly lunar periods, and of solar annual ones. Thus the variolous fever in the natural small-pox commences on the 14th day, and in the inoculated small-pox on the seventh day. The sever and eruption in the distinct kind take up another quarter of a lunation, and the maturation another quarter.

The fever, which is termed canine madness or hydrophobia, is believed to commence near the new or full moon; and, if the cause is not then great enough to bring on the disease, it seems to acquire some strength, or to lie dormant, till another, or perhaps more powerful lunation calls it into action. In the spring, about three or sour years ago, a mad dog very much worried one swine confined in a sty, and bit another in the same sty in a less degree; the sormer became mad, resused his meat, was much convulsed, and died in about four days; this disease commenced about a month after the bite. The other swine began to be ill about a month after the first, and died in the same manner.

Vol. II. ORDO

ORDO III.

Retrograde Associate Motions.

GENUS I.

Catenated with Irritative Motions.

THOSE retrograde affociate motions, the first links of which are catenated with irritative motions, belong to this genus. All the retrograde motions are consequent to debility, or inactivity, of the organ; and therefore properly belong to the genera of decreased actions both in this and the former classes.

SPECIES.

- t. Diabetes irritata. When the absorbents of the intestines are stimulated too strongly by spirit of wine, as in the beginning of drunkenness, the urinary absorbents invert their motions. The same happens from worms in the intestines. In other kinds of diabetes may not the remote cause be the too strong action of the cutaneous absorbents, or of the pulmonary ones? May not in such cases oil externally or internally be of service? or warm bathing for an hour at a time? In hysteric inversions of motion is some other part too much stimulated? or pained from the want of stimulus?
- 2. Sudor frigidus in afthmate. The cause of the paroxysms of humoral assume is not well understood; I suppose it to be owing to a torpidity or inaction of the absorbents belonging to the pulmonary vessels, as happens probably to other viscera at the commencement of intermittent severs, and to a consequent accumulation of sluids in them; which at length producing great irritation or uneasy sensation causes the violent efforts to produce the absorption of it. The motions of the cutaneous absorbent vessels by their association with those of the pulmonary ones become retrograde, and effuse upon the skin a sluid, which is said to be viscid, and which adheres in drops.

A few days ago I saw a young man of delicate constitution in what was called a fit of the asthma; he had about two months before had a peripheumony, and had been ever since subject to difficult respiration on exertion, with occasional palpitation of his heart. He was now seized about eight at night after some exertion of mind in his business with cold extremities, and difficulty of breathing. He gradually became worse, and in about

half

half an hour, the palpitation of his heart and difficult respiration were very alarming; his whole skin was cold and pale, yet he did not shudder as in cold paroxysm of fever; his tongue from the point to the middle became as cold as his other extremities, with cold breath. He seemed to be in the act of dying, except that his pulse continued equal in time, though very quick. He lost three ounces of blood, and took ten drops of laudanum, with musk and salt of hartshorn, and recovered in an hour or two

without any cold fweat.

There being no cold fweat feems to indicate, that there was no accumulation of ferous fluid in the lungs; and that their inactivity, and the coldness of the breath, was owing to the fympathy of the air-cells with some distant part. There was no shuddering produced, because the lungs are not sensible to heat and cold; as any one may observe by going from a warm room into a frosty air, and the contrary. So the steam of hot tea, which fealds the mouth, does not affect the lungs with the fensation of heat. I was induced to believe that the whole cold fit might be owing to suppuration in some part of the chest; as the general difficulty of breathing feemed to be increased after a few days with pulse of 120, and other figns of empyema. Do the cold fweat, and the occurrence of the fits of althma after sleep, distinguish the humoral asthma from the cold paroxysm of intermittents, or that which attends suppuration, or which precedes inflammation?—I heard a few weeks afterwards, that he fpit up much matter at the time he died.

3. Diabetes a timore. The motions of the absorbent vessels of the neck of the bladder become inverted by their confent with those of the skin; which are become torpid by their reverse sympathy with the painful ideas of fear, as in Sect. XVI. 8. 1. whence there is a great discharge of pale urine, as in hysteric

diseases.

The fame happens from anxiety, where the painful suspense is continued, even when the degree of fear is small; as in young men about to be examined for a degree at the universities the frequency of making water is very observable. When this anxiety is attended with a fleepless night, the quantity of pale urine is amazingly great in some people, and the micturition very frequent.

M. M. Opium. Joy. Confolations of friendship.

4. Diarrhæs a timore. The absorbent vessels of the intestines invert their motions by direct confent with the skin; hence many liquid stools as well as much pale urine are liable to accompany continued fear, along with coldness of the skin. The immediate cause of this is the decreased sensorial power of association. ciation, which intervenes between the actions of the absorbents of the cold skin, and those of the intestinal absorbents; the motions of the latter become on that account weakened and at length retrograde. The remote cause is the torpor of the vessels of the skin catenated with the pain of sear, as explained in Sect. XVI. 8. 1.

The capillaries of the skin consent more generally by direct sympathy with those of the lower intestines, and of the bladder; but by reverse sympathy more generally with those of the stomach and upper intestines. As appears in severs, where the hot skin accompanies indigestion of the stomach; and in diarrheeas attended with cold extremities.

The remote cause is the torpor of the skin owing to its reverse sympathy with the painful sensual motions, or ideas, of fear; which are now actuated with great energy, so as to deprive the second link of associated motions of their due share of sensorial power. It is also probable, that the pain of fear itself may contribute to exhaust the sensorial power, even when it produces no muscular action. See Class IV. 2. 2.

5. Pallor et tremor a timore. A retrograde action of the capillaries of the skin producing paleness, and a torpor of the muscular fibres of the limbs occasioning trembling, are caused by their reverse affectations with the ideas or imaginations of fear; which are now actuated with violent energy, and accompanied with great pain. The cause of these affectations are explained in Sect. XVI. 8. 1.

These torpid actions of the capillaries and muscles of the limbs are not caused immediately by the painful sensation of sear; as in that case they would have been increased and not decreased actions, as occurs in anger; where the painful volition increases the actions of the capillaries, exciting a blush and heat of the skin. Whence we may gain some knowledge of what is meant by depressing and exciting passions; the former consisting of ideas attended with pain, which pain occasions no muscular actions, like the pain of cold head-ach; the latter being attended with volitions, and consequent muscular exertions.

That is, the pain of fear, and the pain of anger, are produced by the exertion of certain ideas, or motions of certain nerves of fense; in the former case the painful sensation of fear produces no muscular actions, yet it exhausts or employs so much sensorial power, that the whole system acts more feebly, or becomes retrograde; but some parts of it more so than others, according to their early associations described in Sect. XVI. 8. 1, hence the tremor of the limbs, palpitation of heart, and even syncope. In anger the painful volition produces violent muscular actions;

hase

but if previous to these any deliberation occurs, a stushed countenance sometimes, and a red skin, are produced by this superabundance of volition exerted on the arterial system; but at other times the skin becomes pale, and the legs tremble, from the exhaustion or expenditure of the sensorial power by the painful volitions of anger on the organs of sense, as by the painful sensorial sensorial power by the painful sensorial sensoria

Where the passion of fear exists in a great degree, it exhausts or expends so much sensorial power, either simply by the pain which attends it, or by the violent and perpetual excitement of the terrific imaginations, or ideas, that not only a cold and pale skin, but a retrograde motion of the cutaneous absorbents occurs, and a cold sweat appears upon the whole surface of the body, which probably sometimes increases pulmonary absorption; as in Class II. 1. 6. 4. and as in the cold sweats, which attend the paroxysms of humoral assume. Hence anxiety, which is a continued pain of fear, so universally debilitates the constitution as to occasion a lingering death; which happens much more frequently than is usually supposed; and these victims of continued anxiety are said to die of a broken heart. Other kinds of paleness are described in Class I. 2. 2. 2.

M. M. Opium. Wine. Food. Joy.

6. Palpitatio cordis a timore. The palpitation of the heart from fear is owing to the weak action of it, and perhaps sometimes to the retrograde exertion of the ventricles and auricles; because it seems to be affected by its affociation with the capillaries, the actions of which, with those of the arteries and veins, constitute one great circle of associate motions. Now when the capillaries of the skin become torpid, coldness, and paleness fucceed; and with these are affociated the capillaries of the lungs, whence difficult respiration; and with these the weak and retrograde actions of the heart. At the same time the abforbents of the skin, and of the bladder, and of the intestines, fometimes become retrograde, and regurgitate their contents; as appears by the pale urine in large quantities, which attends hysteric complaints along with this palpitation of the heart; and from the cold sweats, and diarrhoea; all which, as well as the hysteric complaints, are liable to be induced or attended by fear.

When fear has still more violently affected the system, there have been instances where syncope, and sudden death, or a total stoppage of the circulation have succeeded: in these last cases, the pain of fear has employed or exhausted the whole of the sensorial power, so that not only those muscular fibres generally exerted by volition cease to act, whence the patient falls down;

and those which constitute the organs of sense, whence syncope; but lastly those, which perform the vital motions, become deprived of sensorial power, and death ensues. See Class I. 2. I. 4. and I. 2. I. 10. Similar to this in some epileptic fits the patient first suddenly falls down, without even endeavouring to save himself by his hands before the convulsive motions come on. In this case the great exertion of some small part in consequence of great irritation or sensation exhausts the whole sensorial power, which was lodged in the extremities of the locomotive nerves, for a short time, as in syncope; and as soon as these muscles are again supplied, convulsions supervene to relieve the painful sensation. See Class III. 1. 7.

7. Abortio a timore. Women miscarry much more frequently from a fright, than from bodily injury. A torpor or retrograde motion of the capillary arteries of the internal uterus is probably the immediate cause of these miscarriages, owing to the affociation of the actions of those vessels with the capillaries of the skin, which are rendered torpid or retrograde by fear. By this contraction of the uterine arteries, the fine veffels of the placenta, which are inferted into them, are detruded, or otherwife fo affected, that the placenta separates at this time from the uterus, and the fetus dies from want of oxygenation. A strong young woman, in the fifth or fixth month of her pregnancy, who has fince borne many children, went into her cellar to draw beer; one of her fervant boys was hid behind a barrel, and started out to surprise her, believing her to be the maid-fervant; fhe began to flood immediately, and miscarried in a few hours. See Sect. XXXIX. 6. 5. and Class I. 2. 1. 14.

8. Hysteria a timore. Some delicate ladies are liable to fall into hysteric fits from sudden fright. The peristaltic motions of the bowels and stomach, and those of the cesophagus, make a part of the great circle of irritative motions with those of the skin, and many other membranes. Hence when the cutaneous vessels become torpid from their reverse sympathy with the painful ideas of fear; those of the bowels, and stomach, and cesophagus, become first torpid by direct sympathy with those of the skin, and then feebly and inessectually invert the order of their motions, which constitutes a paroxysm of the hysteric distease. See Class I. 3. 1. 10. These hysteric paroxysms are sometimes followed by convulsions, which belong to Class III. as they are exertions to relieve pain; and sometimes by death. See Species 9, of this Genus, and Class I. 2. 1. 4.

Indigestion from fear, is to be ascribed in the same manner to the torpor of the stomach, owing to its association with the

ikin. As in Class IV. 1. 2. 5. IV. 2. 1.

ORDO III.

Retrograde Associate Motions.

GENUS II.

Catenated with Sensitive Motions.

SPECIES.

1. Nausea idealis. Nausea from disgustful ideas, as from hauseous stories, or disgustful sights, or smells, or tastes, as well as vomiting from the same causes, consists in the retrograde actions of the lymphatics of the throat, and of the cefophagus, and stomach; which are affociated with the difgustful ideas, or fenfual motions of fight, or hearing, or fmell, or tafte; for as these are deareafed motions of the lymphatics, or of the œsophagus, or stomach, they cannot immediately be excited by the fenforial power of painful fensation, as in that case they ought to be increased motions. So much sensorial power is employed for a time on the difgustful idea, or expended in the production of inactive pain, which attends it, that the other parts of the affociated chain of action, of which this difgustful idea is now become a link, are deprived of their accustomed share; and therefore first stop, and then invert their motions. Owing to deficiency of sensorial power, as explained more at large in Sect. XXXV. 1. 3.

2. Nausea a conceptu. The nausea, which pregnant women are so subject to during the first part of gestation, is owing to the reverse sympathy between the uterus and stomach, so that the increased action of the former, excited by the stimulus of the growing embryon, which I believe is fometimes attended with fensation, produces decreased actions of the latter with the disagreeable sensation of sickness with indigestion and consequent acidity. When the fetus acquires fo much mufcular power as to move its limbs, or to turn itself, which is called

quickening, this fickness of pregnancy generally ceases.

M. M. Calcined magnefia. Rhubarb. Half a grain of opi-

um twice a day. Recumbent posture on a sofa.

3. Vomitio vertiginosa. Sea-sickness, the irritative motions of vision, by which we balance ourselves, and preserve our perpendicularity, are disturbed by the indistinctness of their objects; which is either owing to the fimilarity of them, or to their diftance, or to their apparent or unufual motions. Hence these irritative motions of vision are exerted with greater energy, and are in consequence attended with sensation; which at first is agreeable, as when children swing on a rope; afterwards the irritative motions of the stomach, and of the absorbent vessels, which open their mouths into it, become inverted by their as-

fociations with them by reverse sympathy.

For the action of vomiting, as well as the disagreeable senfation of sickness, are shewn to be occasioned by defect of the sensorial power; which in this case is owing to the greater expenditure of it by the sense of vision. On the same account the vomiting, which attends the passage of a stone through the ureter, or an inflammation of the bowels, or the commencement of some severs, is caused by the increased expenditure of the sensorial power by the too great action of some links of the affociations of irritative motions; and there being in consequence a desciency of the quantity required for other links of this great catenation.

It must be observed, that the expenditure of sensorial power by the retinas of the eyes is very great; which may be estimated by the perpetual use of those organs during our waking hours, and during most of our sleeping ones; and by the large diameters of the two optic nerves, which are nearly the size of a quill, or equal to some of the principal nerves, which serve the limbs.

4. Vomitio a calculo in uretere. The action of vomiting in confequence of the increased or decreased actions of the ureter, when a stone lodges in it. The natural actions of the stomach, which consist of motions subject to intermitted irritations from the sluids, which pass through it, are associated with those of the ureter; and become torpid, and consequently retrograde, by intervals, when the actions of the ureter become torpid owing to previous great stimulus from the stone it contains; as appears from the vomiting existing when the pain is least. When the motions of the ureter are thus sessent, the sensorial power of association, which ought to actuate the stomach along with the sensorial power of irritation, ceases to be excited into action; and in consequence the actions of the stomach become less energetic, and in consequence retrograde.

For as vomiting is a decreased action of the stomach, as explained in Sect. XXXV. 1. 3. it cannot be supposed to be produced by the pain of gravel in the ureter alone, as it should

then be an increased action, not a decreased one.

The perpetual vomiting in ileus is caused in like manner by the defective excitement of the sensorial power of affociation by

the bowel, which is torpid during the intervals of pain; and the stomach sympathizes with it. See Enteritis, Class II. 1. 2. 11. Does this symptom of vomiting indicate, whether the disease be above or below the valve of the colon? Does not the softer pulse in some kinds of enteritis depend on the sympathy of the heart and arteries with the sickness of the stomach? See Ileus and Cholera.

Hence this fickness, as well as the fickness in some fevers, cannot be esteemed an effort of nature to dislodge any offensive material; but like the sea-fickness described above, and in Sect. XX. 4. is the consequence of the affociations of irritative or sen-

fitive motions. See Class I. 1. 3. 9.

5. Vomitio ab infultu paralytico. Paralytic affections generally commence with vomiting, the fame frequently happens from a violent blow with a stick on the head; this curious connection of the brain and stomach has not been explained; as it resembles the sickness in consequence of vertigo at sea, it would seem to arise from a similar cause, viz. from disturbed irritative or sensitive affociations.

6. Vomitio a titillatione faucium. If the throat be flightly tickled with a feather, a nausea is produced, that is, an inverted action of the mouths of the lymphatics of the fauces, and by direct sympathy an inverted action of the stomach ensues. As these parts have frequently been stimulated at the same time into pleasurable action by the deglutition of our daily aliment, their actions become strongly associated. And as all the food we fwallow, is either moift originally or mixed with our moift faliva in the mouth; a feather, which is originally dry, and which in some measure repels the moist faliva, is disagreeable to the touch of the fauces; at the same time this nausea and vomiting cannot be caused by disagreeable sensation simply, as then they ought to have been increased exertions, and not decreased ones, as shewn in Section XXXV. 1. 3. But the mouths of the lymphatics of the fauces are stimulated by the dry feather into too great action for a time, and become retrograde afterwards by the debility consequent to too great previous stimulus.

7. Vomitio cute sympathetica. Vomiting is successfully stopped by the application of a blister on the back in some fevers, where the extremities are cold, and the skin pale. It was stopped by Sydenham by producing a sweat on the skin by covering the head with the bedclothes. See Class IV. 1. 1. 3. and Suppl.

I. 11. 6.

ORDO III.

Retrograde Affociate Motions.

GENUS III.

Catenated with Voluntary Motions.

SPECIES.

r. Ruminatio. In the rumination of horned cattle the food is brought up from the first stomach by the retrograde motions of the stomach and cesophagus, which are catenated with the vol-

untary motions of the abdominal muscles.

2. Vomitio voluntaria. Voluntary vomiting. Some human fubjects have been faid to have obtained this power of voluntary action over the retrograde motions of the stomach and cesophagus, and thus to have been able to empty their stomach at pleasure. See Sect. XXV. 6. This voluntary act of emptying the stomach is possessed by some birds, as the pigeon; who has an organ for fecreting milk in its stomach, as Mr. Hunter observed; and softens the food for its young by previously swallowing it; and afterwards putting its bill into theirs returns it into their mouths. See Sect. XXXIX. 4. 8. The pelicans use a stomach, or throat bag, for the purpose of bringing the fish, which they catch in the fea to shore, and then eject them, and eat them at their leisure. See Sect. XVI. 11. And I am well informed of a bitch, who having puppies in a stable at a distance from the house, swallowed the flesh-meat, which was given her, in large pieces, and carrying it immediately to her whelps, brought it up out of her stomach, and laid it down before them.

3. Eructatio voluntaria. Voluntary eructation. Some, who have weak digestions, and thence have frequently been induced to eruct the quantity of air discharged from the fermenting aliment in their stomachs, have gradually obtained a power of voluntary eructation, and have been able thus to bring up hogsheads of air from their stomachs whenever they pleased. This great quantity of air is to be ascribed to the increase of the fermentation of the aliment by drawing off the gas as soon as it is

Old San Phone and A.T.

And Array and the same of the

ORDO III.

Retrograde Associate Motions.

GENUS IV.

Catenated with External Influences.

SPECIES.

1. Catarrhus periodicus. Periodical catarrh is not a very uncommon disease; there is a great discharge of a thin saline mucous material from the membranes of the nostrils, and probably from the maxillary and frontal sinuses, which recur once a day at exact solar periods; unless it be disturbed by exhibition of opium; and resembles the periodic cough mentioned below. See Class I. 3. 2. 1. It is probably owing to the retrograde action of the lymphatics of the membranes affected, and produced

immediately by folar influence.

2. Tuffis periodica. Periodic cough, called nervous cough, and tuffis ferina. It feems to arife from a periodic retrograde action of the lymphatics of the membrane, which lines the aircells of the lungs. And the action of coughing, which is violent for an hour or longer, is probably excited by the stimulus of the thin sluid thus produced, as well as by the disagreeable fensation attending membranous inactivity; and resembles periodic catarrh not only in its situation on a mucous membrane, but in the discharge of a thin sluid. As it is partly restrainable, it does not come under the name of convulsion; and as it is not attended with difficult respiration, it cannot be called as thin it is cured by very large doses of opium, see a case and cure in Sect. XXXVI. 3. 9. Class IV. 2. 4. 6. and seems immediately to be induced by solar influence.

3. Hysteria a frigore. Hysteric paroxysms are occasioned by whatever suddenly debilitates the system, as fear, or cold, and perhaps sometimes by external moisture of the air, as all delicate people have their days of greater or less debility, see Class IV.

3-1.8.

4. Nausea pluvialis. Sickness at the commencement of a rainy season is very common among dogs, who assist themselves by eating the agrostis canina, or dog's grass, and thus empty their stomachs. The same occurs with less frequency to cats, who make use of the same expedient. See Sect. XVI. 11. I have known one person, who from his early years has always

ocen

THE OWNER OF THE OWNER, THE OWNER

A STATE OF THE PARTY OF THE PAR

been fick at the beginning of wet weather, and still continues so. Is this owing to a sympathy of the mucous membrane of the stomach with the mechanical relaxation of the external cuticle by a moister atmosphere, as is seen in the corrugated cuticle of the hands of washer-women? or does it sympathize with the mucous membrane of the lungs, which must be affected along with the mucus on its surface by the respiration of a moister atmosphere.

The second secon

SUPPLEMENT

TO

CLASSIV.

Sympathetic Theory of Fever.

As fever consists in the increase or diminution of direct or reverse associated motions, whatever may have been the remote cause of them, it properly belongs to the fourth class of diseases; and is introduced at the end of the class, that its great difficulties might receive elucidation from the preceding parts of it. These I shall endeavour to enumerate under the following heads, trusting that the candid reader will discover in these rudiments of the theory of sever a nascent embryon, an infant Hercules, which Time may rear to maturity, and render serviceable to mankind.

I. Simple fever of two kinds.

II. Compound fever.

III. Termination of the cold fit,

IV. Return of the cold fit.

V. Sensation excited in fever.

VI. Circles of affociated motions.

VII. Alternations of cold and hot fits.

. VIII. Orgafm of the capillaries.

X. Torpor of the lungs.

XI. Torpor of the heart and arteries.

XII. Torpor of the stomach and intestines.

XIII. Case of continued sever explained.

XIV. Termination of continued fever. XV. Inflammation excited in fever.

XVI. Recapitulation.

I. Simple Fever.

1. When a small part of the cutaneous capillaries with their mucous or perspirative glands are for a short time exposed to a colder medium, as when the hands are immersed in iced water

for a minute, thefe capillary vessels and their glands become torpid or quiescent, owing to the eduction of the stimulus of heat. The skin then becomes pale, because no blood passes through the external capillaries; and appears shrunk, because their sides are collapsed from inactivity, not contracted by spasm; the roots of the hair are left prominent from the seceding or subfiding of the skin around them; and the pain of coldness is produced.

In this fituation, if the usual degree of warmth be applied, these yessels regain their activity; and having now become more irritable from an accumulation of the fenforial power of irritation during their quiescence, a greater exertion of them follows, with an increased glow of the skin, and another kind of pain. which is called the hot-ach; but no fever, properly fo called, is yet produced; as this effect is not univerfal, nor permanent, nor recurrent.

2. If a greater part of the cutaneous capillaries with their mucous and perspirative glands be exposed for a longer time to cold, the torpor or quiescence becomes extended by direct sympathy to the heart and arteries; which is known by the weakness, and consequent frequency of the pulse in cold fits of fever.

This requires to be further explained. The movements of the heart and arteries, and the whole of the circulatory vessels, are in general excited into action by the two fenforial powers of irritation, and of affociation. The former is excited by stimulus, the latter by the previous actions of a part of the vital circle of motions. In the above fituation the capillaries act weakly from defect of irritation, which is caused by deficient stimulus of heat; but the heart and arteries act weakly from defect of affociation, which is owing to the weak action of the capillarics; which does not now excite the fenforial power of affocia-

tion into action with fusficient energy.

After a time, either by the application of warmth, or by the increase of their irritability owing to the accumulation of the fenforial power of irritation during their previous quiescence, the capillary vessels and glands act with greater energy than natural; whence the red colour and heat of the skin. The heart and arteries acquire a greater strength of pulsation, and continue the frequency of it, owing to the accumulation of the fenforial power of affociation during their previous torpor, and their confequent greater affociability; which is now also more strongly excited by the increased actions of the capillaries. And thus a fit of simple fever is produced, which is termed Febris irritativa; and confifts of a torpor of the cutaneous capillaries with their mucous and perspirable glands, accompanied with a torpor of the heart and arteries; and afterwards of an increased action of all these vessels, by what is termed direct sympathy.

This fever, with throng pulse without inflammation, or febris irritativa, described in Class I. 1. 1. 1. is frequently seen in vernal intermittents, as the orgain of the heart and arteries is then occasioned by their previous state of torpor; but more rarely I believe exists in the type of continued fever, except there be an evident remission, or approximation to a cold fit; at which time a new accumulation of the fenforial power of affociation is produced: which afterwards actuates the heart and arteries with unnatural vigour; or unless there be some stimulus perpetually acting on the fystem, so as to induce an increased secretion of fenforial power in the brain, as occurs in flight degrees of intoxication. Since without one or other of these circumstances in continued fevers without inflammation, that is, without the additional fenforial power of fenfation being introduced, it feems difficult to account for the production of fo great a quantity of sensorial power, as must be necessary to give perpetual increase

of action to the whole fanguiferous system.

3. On the contrary, while the cutaneous capillaries with their mucous and perspirative glands acquire an increased irritability, as above, by the accumulation of that fenforial power during their previous quiescence, and thus constitute the hot fit of fever; if the heart and arteries do not acquire any increase of asfociability, but continue in their state of torpor, another kind of simple fever is produced; which is generally of the continued kind, and is termed Febris inirritativa; which confifts of a previous torpor of the capillaries of the skin, and of the heart and arteries by direct sympathy with them; and afterwards of an orgasm or increased action of the capillaries of the skin, with a decreased action, or continued torpor, of the heart and arteries by reverse sympathy with them. This orgasm of the cutaneous capillaries, which appears by the blush and heat of the skin, is at first owing to the accumulation of the sensorial power of irritation during their previous torpid state; as in the febris irritata above described; but which is afterwards supported or continued by the reverse sympathy of these capillaries with the torpid state of the heart and arteries, as will be further explained in article 8. of this Supplement.

4. The renovated activity of the capillaries commences ar foon or fooner than that of the heart and arteries after the cold fit of irritative fever; and is not owing to their being forced open by the blood being impelled into them mechanically, by the renovated action of the heart and arteries; for these capillaries of the skin have greater mobility than the heart and arte-

ries, as appears in the fudden blush of shame; which may be owing to their being more liable to perpetual varieties of activity from their exposure to the vicissitudes of atmospheric heat. And because in inirritative severs, or those with arterial debility, the capillaries acquire increased strength, as is evinced by the heat of the skin, while the pulsations of the heart and arteries remain feeble.

5. It was faid above, that the cutaneous capillaries, when they were rendered torpid by exposure to cold, either recovered their activity by the reapplication of external warmth; or by their increased irritability, which is caused by the accumulation of that fenforial power during their quiescence. An example of the former of these may be seen on emerging from a very cold bath; which produces a fit of simple fever; the cold fit, and confequent hot fit, of which may be prolonged by continuing in the bath; which has indeed proved fatal to fome weak and delicate people, and to others after having been much exhausted by heat and exercise. See Sect. XXXII. 3. 2. An example of the latter may be taken from going into a bath of about eighty degrees of heat, as into the bath at Buxton, where the bather first feels a chill, and after a minute becomes warm, though he remains in the fame medium, owing to the increase of irritability from the accumulation of that fenforial power during the Thort time which the chilness continued.

6. Hence simple fevers are of two kinds; first, the febris irritativa, or fever with strong pulse; which consists of a previous torpor of the heart, arteries, and capillaries, and a succeeding orgasm of those vessels. Secondly, the febris inirritativa, or fever with weak pulse, which consists of a previous torpor of the heart, arteries, and capillaries; and of a succeeding orgasm of the capillaries, the torpor of the heart and arteries continuing. But as the frequency of the pulse occurs both in the state of torpor, and in that of orgasm, of the heart and arteries; this constitutes a criterion to distinguish fever from other diseases, which are owing to the torpor of some parts of the system, as paresis,

and hemicrania.

7. The reader will please to observe, that where the cutaneous or pulmonary capillaries are mentioned, their mucous and perspirative glands are to be understood as included; but that the absorbents belonging to those systems of vessels, and the commencement of the veins, are not always included; as these are liable to torpor separately, as in anasarca, and petechiæ; or to orgasm, or increased action, as in the exhibition of strong emetics, or in the application of vinegar to the lips; yet he will also please to observe, that an increased or decreased action of

thefe

these absorbents and veins generally occurs along with that of the capillaries, as appears by the dry skin in hot fits of fever; and from there being generally at the same time no accumulation of venous blood in the cutaneous vessels, which would appear by its purple colour.

II. Compound Fever.

1. When other parts of the system sympathize with this torpor and orgafin of the cutaneous capillaries, and of the heart and arteries; the fever-fit becomes more complicated and dangerous; and this in proportion to the number and consequence of fuch affected parts. Thus if the lungs become affected, as in going into very cold water, a shortness of breath occurs: which is owing to the collapse or inactivity (not to the active contraction, or spasm), of the pulmonary capillaries; which, as the lungs are not sensible to cold, are not subject to painful fensation, and consequent shuddering, like the skin. In this case after a time the pulmonary capillaries, like the cutaneous ones. act with increased energy; the breathing, which was before quick, and the air thrown out at each respiration in less quantity, and cool to the back of the hand opposed to it, now becomes larger in quantity, and warmer than natural; which however is not accompanied with the fensation of heat in the membrane, which lines the air-vessels of the lungs, as in the skin.

2. One consequence of this increased heat of the breath is the increased evaporation of the mucus on the tongue and nos-A viscid materal is secreted by these membranes to preferve them moist and supple, for the purposes of the senses of taste and of smell, which are extended beneath their surfaces a this viscid mucus, when the aqueous part of it is evaporated by the increased heat of the respired air, or is absorbed by the too great action of the mucous absorbents, adheres closely on those membranes, and is not without difficulty to be separated from them. This dryness of the tongue and nostrils is a circumstance therefore worthy to be attended to; as it shews the increased action of the pulmonary capillaties, and the consequent increased heat of the expired air; and may thus indicate, when colder air should be admitted to the patient. See Class I. 1. 3. 1. The middle part of the tongue becomes dry fooner, and recovers its moisture later, than the edges of it; because the currents of respired air pais most over the middle part of it. This however is not the case, when the dryne's of the tongue is owing only to the increased mucous absorption. When however a frequent cough attends pulmonary inflammation, the edges of

VOL. II. KKK the tongue are liable to be as much furred as the middle of it; as during the action of coughing the middle of the tongue is depressed, so as to form half a cylinder, to give a greater aperture for the emission of air from the larynx; and the edges of it become thus as much exposed to the currents of air as the middle

3. When the internal capillaries or glands fympathize with the cutaneous capillaries; or when any of them are previously affected with torpor, and the external or cutaneous capillaries are affected fecondarily; other symptoms are produced, which render the paroxysms of fever still more complicate. Thus if the spleen or pancreas are primarily or secondarily affected, so as to be rendered torpid or quiescent, they are liable to become enlarged, and to remain so even after the extinction of the feverfit. These in some intermittent fevers are perceptible to the hand, and are called ague-cakes; their tumour feems to be owing to the permanent torpor of the absorbent system, the secerning vessels continuing to act some time afterwards. If the secretory vessels of the liver are affected first with torpor, and afterwards with orgafm, a greater fecretion of bile is produced, which sometimes causes a diarrhoea. If a torpor of the kidneys, and of the absorbents of the bladder occurs, either primarily, or by fympathy with the cutaneous capillaries, the urine is in small quantity and pale, as explained in Class I. 2. 2. 5.; and if these fecretory vessels of the kidneys, and the absorbents of the bladder act more strongly than natural afterwards by their increased irritability or affociability, the urine becomes in larger quantity, and deeper coloured, or deposits its earthy parts, as in Class I. 1. 2. A. which has been esteemed a favourable circumstance. But if the urine be in small quantity, and no sediment appears in it, after the hot fit is over; it shews that the secerning vessels of the kidneys and the absorbent vessels of the bladder have not regained the whole of their activity, and thence indicates a greater tendency to a return of the cold fit.

4. When the stomach is affected with torpor either primarily; or secondarily by its sympathy with the cutaneous capillaries; or with some internal viscus; sickness occurs, with a total want of appetite to any thing solid; vomiting then supervenes, which may often be relieved by a blister on the skin, if the skin be cool and pale; but not if it be hot and sushed. The intestines cease to perform their office of absorption from a similar torpor; and a diarrhea supervenes owing to the acrimony of their putrid, or of their acid contents. The loose undigested or fetid stools indicate the inability of the intestines to perform their proper office; as the mucus and gastric acid, which are

vomitee

vomited up, does that of the stomach; this torpor of the stomach is liable to continue after the cold paroxylm ceases, and to convert intermittent fevers into continued ones by its direct fympathy with the heart and arteries. See article 10. of this

Supplement.

5. If the meninges of the brain fympathize with other torpid parts, or are primarily affected, delirium, stupor, and perhaps hydrocephalus internus, occur, see Class II. 1. 7. 1. and I. 2. 5. 10; and sometimes the pulse becomes slow, producing paresis instead of fever. But if the membranes, which cover the muscles about the head, or of the pericranium, become torpid by their sympathy with other torpid parts, or are primarily affected, a head-ach fupervenes; which however generally ceases with the cold paroxysm of sever. For as when the sensorial power of volition is exhausted by labour, a few hours, or half a folar day, passed in sleep recruits the system by accumulation of this fenforial power; fo when the fenforial power of irritation is exhausted, one or two solar or lunar days of rest or quiescence of the affected part will generally restore its action by accumulation of irritability, and confequent increase of affociation, as in hemicrania, Class IV. 2. 2. 8. But when the heart and arteries become torpid, either primarily, or by their fympathy with the stomach, this accumulation of the fenforial power of irritation can take place but flowly; as to rest is death! This explains the cause of the duration of fevers with weak pulse, which continue a quarter, or half, or three quarters, or a whole lunation, or still longer, before fufficient accumulation of irritability can be produced to restore their natural strength of action.

6. If the absorbent vessels, which are spread around the neck of the bladder, become torpid by their direct sympathy with the absorbents of the skin in cold fits of fever; the urine, which is poured into the bladder in but small quantity from the torpid kidneys, has nevertheless none of its aqueous saline part reabforbed; and this faline part stimulates the bladder to empty itfelf frequently, though the urine is in small quantity. Which is not therefore owing to any supposed spasm of the bladder, for the action of it in excluding the urine is weak, and as much con-

trollable by the will as in ordinary micturition.

7. If the beginnings or absorbent mouths of the venous systtem remain torpid, petechiæ or vibices are produced in fevers, fimilar to those which are seen in scurvy without sever. If the skin was frequently moistened for an hour, and at the same time exposed to the common air, or to oxygen gas, it might contribute to turn the black colour of these points of extravasated blood into scarlet, and thus by increasing its stimulus facilitate its reabsorption? For oxygen gas penetrates moist animal membranes though not dry ones, as in the lungs during respiration.

See Class I. 2. 41.17.

8. When the fenforial power of fenfation is introduced into the arterial system, other kinds of compound fevers are produced, which will be spoken of in their place.

III. Termination of the cold Fit.

1. If all the parts, which were affected with torpor, regain their irritability, and affociability, the cold paroxysm of fever ceases; but as some of the parts affe ted were previously accustomed to incessant action, as the heart and arteries, and others only to intermitted action, as the stomach and intestines; and as those, which are subjected during health to perpetual action, accumulate sensorial power faster, when their motions are impeded, than those which are subjected to intermitted action; it happens, that some of the parts, which were affected with torpor during the cold sit, recover their irritability or associability some than others, and more perfectly, or acquire a greater quantity of them than natural; as appears by the partial heat and slushings previous to the general hot sit.

Hence if all the parts, which were previously torpid, regain their due degree of irritability, or of affociability, the disease is removed, and health restored. If some or all of them acquire more than their natural degree of these sensorial powers; increased actions, and consequent increased secretions, and greater heat occur, and constitute the hot sit of sever. If after this hot sit of sever all the parts, which had acquired too great irritability, or associability, regain their natural degree of it; the disease is removed, and health restored. But if some of these parts do not regain their natural degree of these sensorial powers, the actions of those parts remain imperfect, and are more or less injurious to the system, according to the importance of their

functions.

2. Thus if a torpor of the heart and arteries remains; the quick pulse without strength, which began in the cold fit, per-fists; and a continued sever is produced. If the torpor of the stomach and intestines remains, which is known by sickness and undigested stools, the sever is liable to be of considerable length and danger; the same if the kidneys and absorbent system retain some degree of torpor, as is shewn by the pale urine in not unusual quantity. If part of the absorbent system remains torpid, as the absorbent vessels of the spleen, a tumour of that viscus occurs, which may be felt by the hand; the same some

times

times happens to the liver; and these from their tendency to more complete torpor are afterwards liable to give occasion to a return of the cold fit. If the cellular absorbents do not completely recover their activity, a pale and bloated countenance with swelled legs marks their want of action.

3. As the termination of the cold fit is owing to the accumulation of the fenforial power of irritation and of affociation during the previous quiescence of the system; and as those parts, which are in perpetual action during health, are more subject to this accumulation during their torpor, or quiescence; one should have imagined, that the heart and arteries would acquire this accumulation of sensorial power sooner or in greater degree than other parts. This indeed so happens, where the pulse is previously strong, as in febris irritativa; or where another sensorial power, as that of sensorial power, as that of sensorial power, as in inflammations. The heart and arteries in these cases soon recover from their torpor, and are exerted with great violence.

Many other parts of the fystem subject to perpetual motion in health may rest for a time without much inconvenience to the whole; as when the singers of some people become cold and pale; and during this complete rest great accumulation of irritability may be produced. But where the heart and arteries are previously feeble, they cannot much diminish their actions, and certainly cannot rest entirely, for that would be death; and therefore in this case their accumulation of the sensorial power of irritation or of association is slowly produced, and a long sever supervenes in consequence; or sudden death,

as frequently happens, terminates the cold fit.

Whence it appears, that in fevers with weak pulse, if the action of the heart, arteries, and capillaries could be diminished, or stopped for a short time without occasioning the death of the patient, as happens in cold bathing, or to persons apparently drowned, that a great accumulation of the sensorial powers of irritation or of association might soon be produced, and the pulse become stronger, and consequently slower, and the fever cease. Hence cold ablution may be of service in severs with weak pulse, by preventing the expenditure and producing accumulation of the sensorial power of irritation or association. Stupor may be useful on the same account. Could a centrifugal swing be serviceable for this purpose, either by placing the head or the seet in the outward part of the circle, as described in Art. 15. 7: of this Supplement?

IV. Return of the cold Fit.

- 1. If the increased action of the cutaneous and pulmonary capillaries, and of the heart and arteries, in febris irritativa, continues long and with violence, a proportional expenditure or exhaustion of fensorial power occurs; which by its tendency to induce torpor of some part, or of the whole, brings on a return of the cold sit.
- 2. Another cause which contributes to induce torpor of the whole system by the sympathy of its parts with each other, is the remaining torpor of some viscus; which after the last cold paroxysm had not recovered itself, as of the spleen, liver, kidneys, or of the stomach and intestines, or absorbent vessels, as above mentioned.
- 3. Other causes are the deficiency of the natural stimuli, as hunger, thirst, and want of fresh air. Other causes are great fatigue, want of rest, fear, grief, or anxiety of mind. And lastly, the influence of external ethereal sluids, as the defect of external heat, and of solar or lunar gravitation. Of the latter the return of the paroxysms of continued severs about six o'clock in the evening, when the solar gravitation is the least, affords an example of the influence of it; and the usual periods of intermittents, whether quotidian, tertian, or quartan, which so regularly obey solar or lunar days, afford instances of the influence of those luminaries on these kinds of severs.
- 4. If the tendency to torpor of some viscus is considerable, this will be increased at the time, when the terrene gravitation is greatest, as explained in the introduction to Class IV. 2. 4. and may either produce a cold paroxysm of quotidian sever; or it may not yet be sufficient in quantity for that purpose, but may nevertheless become greater, and continue so till the next period of the greatest terrene gravitation, and may then either produce a paroxysm of tertian sever; or may still become greater, and continue so till the next period of greatest terrene gravitation, and then produce a paroxysm of quartan ague. And lastly, the periodical times of these paroxysms may exceed, or fall short of, the time of greatest diurnal terrene gravitation according to the time of day, or period of the moon, in which the first sit began; that is, whether the diurnal terrene gravitation was then in an increasing or decreasing state.

V. Sensation excited in Fever.

1. A curious observation is related by Dr. Fordyce in his

Tract on Simple fever, page 168. He afferts, that those people. who have been confined some time in a very warm atmosphere, as of 120 or 130 degrees of heat, do not feel cold, nor are fubiect to paleness of their skins, on coming into a temperature of 30 or 40 degrees; which would produce great paleness and painful fensation of coldness in those, who had been some time confined in an atmosphere of only 86 or 90 degrees. Analogous to this, an observing friend of mine assured me, that once having fat up to a very late hour with three or four very ingenious and humorous companions, and drunk a considerable quantity of wine; both contrary to his usual habits of life; and being obliged to rife early, and to ride a long journey on the next day; he expected to have found himfelf weak and foon fatigued; but on the contrary he performed his journey with unufual ease and alacrity; and frequently laughed, as he rode, at the wit of the preceding evening. In both these cases a degree of pain or pleasure actuated the system; and thus a sensorial power, that of fensation, was superadded to that of irritation, or volition. See Sect. XXXIV. 2. 6.

2. Similar to this, when the energetic exertions of some parts of the fystem in the hot sit of sever arise to a certain excess, a degree of sensation is produced; as of heat which particularly increases the actions of the cutaneous vessels, which are more liable to be excited by this stimulus. When this additional sensorial power of sensation exists to a greater degree, the pulse, which was before full, now becomes hard, owing to the inflammation of the vasa vasorum, or coats of the arteries. In these cases whether there is any topical inflammation or not, the sever ceases to intermit; but nevertheless there are daily remissions and exacerbations of it; which recur for the most part about six in the evening, when the solar gravitation is the least, as mention-

ed in Sect. XXXVI. 3. 7.

3. Thus the introduction of another fenforial power, that of fenfation, converts an intermittent fever into a continued one. If it be attended with strong pulse, it is termed febris fensitiva irritata, or pyrexia, or inflammation; if with a weak pulse, is is termed febris fensitiva inirritata, or typhus gravior, or malignant fever. The feat of the inflammation is in the glandular or capillary system, as it consists in the secretion of new sluids, or new sibres, which form new vessels, as they harden, like the silk of the silk-worm. See Art. 15. of this Supplement.

VI. Circles of irritative Affectate Motions.

1. There are some affociate motions, which are perpetually proceeding

proceeding in our waking hours, and are catenated by their first link, or in some subsequent parts of the chain, with the stimuli or the influence of external things; which we shall here enumerate, as they contribute to the knowledge of sever. Of these are the irritative ideas, or sensual motions of the organs of sense, and the muscular motions associated with them; which, when the chain is disturbed or interrupted, excite the sensorial power of sensation, and proceed in consusion. Thus if the irritative ideas of sight are disturbed, the paralactic motions of objects, which in general are unperceived, becomes sensible to us; and the locomotive muscles associated with them, which ought to preserve the body erect, stagger from this decrease or interruption of the sensorial power of association; and vertigo is produced.

When the irritative fensual motions, or ideas, belonging to one fense are increased or diminished, the irritative sensual motions, or ideas, of the other senses are liable to become disturbed by their general catenations; whence occur noises in the ears, bad tastes in the mouth, bad odours, and numbers or tingling of the limbs, as a greater or less number of senses are affected. These constitute concomitant circles of disturbed irritative ideas; or make a part of the great circle of irritative ideas, or motions of the organs of sense; and when thus disturbed occasion many kinds of hallucination of our other senses, or attend on the vertigo of vision.

2. Another great circle of irritative affociated motions confifts of those of the alimentary canal; which are catenated with stimuli or with influences external to the system, but continue to be exerted in our sleeping as well as in our waking hours. When these affociations of motion are disturbed by the too great or too small stimulus of the food taken into the stomach, or by the too great excess or deprivation of heat, or by indigestible substances, or by torpor or orgasm occasioned by their association with other parts, various diseases are induced under the names of apepsia, hypochondriasis, hysteria, diarrheea, cholera, ileus, nephritis, fever.

3. A third circle of irritative affociate motions confifts of those of the absorbent system; which may be divided into two, the lacteals, and the lymphatics. When the stomach and intestines are recently filled with food and fluid, the lacteal system is stimulated into great action; at the same time the cellular, cutaneous, and pulmonary lymphatics act with less energy; because less sluid is then wanted from those branches, and because more tensorial power is expended by the lacteal branch. On this account these two systems of absorbents are liable to act by re-

verse sympathy; hence pale urine is made after a full dinner, as less of the aqueous part of it is imbibed by the urinary lymphatics; and hence the water in anasarca of the lungs and limbs is speedily absorbed, when the actions of the lacteals of the stomach or intestines are weakened or inverted by the exhibition of those drugs, which produce nausea, or by violent vomiting, or violent cathartics.

Hence in diabetes the lacteal fystem acts strongly, at the same time that the urinary lymphatics invert their motions, and transmit the chyle into the bladder; and in diarrhea from crapula, or too great a quantity of food and sluid taken at a time, the lacteals act strongly, and absorb chyle or sluids from the stomach and upper intestines; while the lymphatics of the lower intestines revert their motions, and transmit this over-repletion into the lower intestines, and thus produce diarrhea; which accounts for the speedy operation of some cathartic drugs, when

much fluid is taken along with them.

4. Other circles of irritative affociate motions of great importance are those of the secreting system; of these are the motions of the larger congeries of glands, which form the liver, spleen, pancreas, gastric glands, kidneys, salivary glands, and many others; some of which act by direct and others by reverse sympathy with each other. Thus when the gastric glands act most powerfully, as when the stomach is silled with food, the kidneys act with less energy; as is shewn by the small secretion of urine for the first hour or two after dinner; which reverse sympathy is occasioned by the greater expenditure of sensorial power on the gastric glands, and to the newly absorbed sluids not yet being sufficiently animalized, or otherwise prepared, to stimulate the secretory vessels of the kidneys.

But those very extensive glands, which secrete the perspirable matter of the skin and lungs, with the mucus, which lubricates all the internal cells and cavities of the body, claim our particular attention. These glands, as well as all the others, proceed from the capillary vessels which unite the arteries with the veins, and are not properly a part of them; the mucous and perspirative glands, which arise from the cutaneous and pulmonary capillaries, are associated by direct sympathy; as appears from immersion in the cold bath, which is therefore attended with a temporary difficult respiration; while those from the capillaries of the stomach and heart and arteries are more generally associated by reverse sympathy with those of the cutaneous capillaries; as appears in severs with weak pulse and indigestion, and at the same time with hot and dry skin.

The disturbed actions of this circle of the affociate motions of Vol. II.

the fecerning fystem, when the sensorial power of sensation is added to that of iritation, frequently produces inflammation, which consists in the secretion of new sluids or new vessels. Nevertheless, if these disturbed actions be of the torpid kind, the pain, which attends them, is seldom productive of inflammation, as in hemicrania; but is liable to excite voluntary actions, and thus to expend much sensorial power, as in the shuddering in cold fits of sever, or in convulsions; or lastly the pain itself, which attends torpid actions, is liable to expend or exhaust much sensorial power without producing any increased actions; whence the low pulse, and cold extremities, which usually attend hemicrania; and hence when inert, or inactive sensorial tends one link of associated action, the succeeding link is generally rendered torpid, as a coldness of the cheek attends tooth-ach.

5. A fifth important circle of irritative motions is that of the fanguiferous fystem, in which the capillary vessels are to be included, which unite the arterial and venous systems, both pulmonary and aortal. The disturbed action of this system of the heart and arteries, and capillaries, constitutes simple fever; to which may be added, that the secenting and absorbent vessels appending to the capillaries, and the bibulous mouths of the veins, are in some measure at the same time generally affected.

6. Now, though the links of each of these circles of irritative motions are more strictly associated together, yet are they in greater or less degree associated or catenated with each other by direct or reverse sympathy. Thus the sickness, or inverted irritative motions of the stomach, are associated or catenated with the disturbed irritative ideas, or sensual motions, in vertigo; as in sea-sickness. This sickness of the stomach is also associated or catenated with the torpor of the heart and arteries by direct sympathy, and with the capillaries and absorbents by reverse sympathy; and are thus all of them liable occasionally to be disturbed, when one of them is diseased; and constitute the great variety of the kinds or symptoms of severs.

VII. Alternation of the cold and hot Fits.

1. When any cause occurs, which diminishes to a certain degree the supply of sensorial power in respect to the whole system; as suppose a temporary inexertion of the brain; what happens? First, those motions are exerted with less energy, which are not immediately necessary to life, as the locomotive muscles; and those ideas, which are generally excited by volition; at the same time this deficiency of voluntary motion is

different from that which occurs in fleep; as in that the movements of the arterial fystem are increased in energy though not in frequency. Next, the motions of the alimentary canal become performed with less energy, or cease altogether; and a total want of appetite to solid food occurs, or sickness or a diarrhea occasioned by the indigested aliment. Then the absorbent vessels cease to act with their due energy; whence thirst, and pale urine, though in small quantities. Fourthly, the secential power; whence all the secreted sluids are produced in less quantity. And lastly, the sanguiserous canals feel the general torpor; the pulsations of the heart and arteries become feeble, and consequently quick; and the capillaries of the skin become inactive, acquire less blood from the arteries, and are consequently paler and shrunk.

In this last circumstance of the torpor of the sanguiserous system consists inirritative sever; as all the others are rather accidental or concomitant symptoms, and not essential ones; as sewer or more of them may be present, or may exist with a

greater or less degree of inactivity.

2. Now as the capillaries of the skin are exposed to greater varieties of heat and cold, than the heart and arteries, they are supposed to be more mobile, that is, more susceptible of torpor or exertion, or to inflammation, by external stimuli or influences, than the other parts of the sanguiserous system; and as the skin is more sensible to the presence of heat, than the internal parts of the body, the commencement of the cold paroxysms of sever generally either first exists in, or is first perceived by, the coldness and paleness of the skin; and the commencement of the hot sits by the heat and redness of it.

3. The accumulation of fenforial power occurs in these organs soonest, and in greatest quantity, during their quiescence, which were most perpetually in action during health; hence those parts of the system soonest recover from torpor in intermittent sever, and soonest fall into the contrary extreme of increased activity; as the sanguiserous system of the heart and arteries and capillaries. But of these the capillaries seem first to acquire a renovation of their action, as the heat of the skin becomes first renewed, as well as increased beyond its natural quantity, and this in some parts sooner than in others; which quantity of heat is however not to be estimated simply by the rise of the mercury in the thermometer, but also by the quantity carried away into the atmosphere, or disfused amongst other bodies in a given time; as more heat passes through water, which boils vehemently, than when it boils gently, though the

rife of the thermometer in both cases continues the same. This fact may be known by boiling an egg in water, the white of which coagulates in much less time, if the water boils vehemently, than if it boils moderately, though the sensible heat of the water is the same in both cases.

Another cause, which induces the cutaneous capillaries to renew their actions sooner than the heart and arteries after immersion in the cold bath, is, that their torpor was occasioned by defect of irritation: whereas that of the heart and arteries was occasioned by defect of association; which desect of association was owing to the decreased actions of the capillaries, and is now again excited by their renewed action; which excitement must therefore be subsequent to that increased action of the capillaries; and in consequence the increased action of the heart and arteries at the commencement of the hot sit of some severs is subsequent to the increased action of the cutaneous capillaries. There is, however, in this case an accumulation of the sensorial power of association in the heart and arteries, which must contribute to increase their orgasm in the hot sit, as well as the increased excitement of it by the increased action of the capillaries.

4. Now this increased action of the system, during the hot fit, by exhausting the sensorial powers of irritation and association, contributes to induce a renewal of the cold paroxysm; as the accumulation of those sensorial powers in the cold sit produces the increased actions of the hot sit; which two states of the system reciprocally induce each other by a kind of libration, or a plus and minus, of the sensorial powers of irritation and

affociation.

If the exhaustion of fensorial power during the hot fit of fever only reduces the quantity of irritability and affociability to its natural standard, the sever is cured, not being liable to return. If the quantity of these sensorial powers be reduced only so much, as not to produce a second cold fit during the present quantity of external stimuli or influences; yet it may be so far reduced, that a very small subtraction of stimulus, or of insluence, may again induce a cold fit; such as the coldness of the night-air, or the diminution of solar or lunar gravitation, as in intermittent severs.

5. Another cause of the renovation of the cold fits of sever is from some parts of the system not having completely recovered from the former cold paroxysm; as happens to the spleen, liver, or other internal viscus; which sometimes remains tumid, and either occasions a return of the cold fit by direct sympathy with other parts of the body, or by its own want of action causes a diminution of the general quantity of heat, and thus facility

tates the renovation of the torpor of the whole fystem, and gives cause to intermittent fevers catenated with lunar or solar influ-

VIII. Orgafm of the Capillaries.

As the remaining torpor of some less essential part of the system, as of the spleen, when the hot fit ceases, produces after one, two, or three days a return of cold fit by direct sympathy with the cutaneous capillaries, when joined with some other cause of torpor, as the defect of solar or lunar influences, or the exposure to cold or hunger, and thus gives origin to intermittent fever; so the remaining torpor of some more essential parts of the fystem, as of the stomach and intestines, is probably the cause of the immediate recurrence of the cold paroxysm, at the time the hot one ceases, by their direct sympathy with the cutaneous capillaries, without the affiftance of any other cause of torpor; and thus produces remittent fever. And lastly the remaining torpor of some still more essential parts of the system. as the heart and arteries, after the hot fit ought to cease, is liable by reverse sympathy with the cutaneous capillaries to continue their orgafm, and thus to render a fever continual, which would otherwise remit or intermit.

Many difficulties here occur, which we shall endeavour to throw some light upon, and leave to suture investigation; obferving only that difficulties were to be expected, otherwise fevers would long fince have been understood, as they have employed the unremitted attention of the physicians of all ages of

1. Why do the same parts of successive trains of action sometimes affect each other by direct, and fometimes by reverle fympathy?-1st, When any irritative motion ceases, or becomes torpid, which was before in perpetual action; it is either deprived of its usual stimulus, and thence the sensorial power of irritation is not excited; or it has been previously too much stimulated, and the sensorial power has been thus exhausted.

In the former case an accumulation of sensorial power soon, occurs, which is excitable by a renewal of the stimulus; as when the fingers, which have been immerfed fome time in fnow, are again exposed to the usual warmth of a room. Or, secondly, the fenforial power of irritation becomes fo much accumulated, that the motions, which were torpid, are now performed by less stimulus than natural; as appears by the warmth, which foon: occurs after the first chill in going into frosty air, or into the bath at Buxton, which is about eighty degrees of heat. Or,

laftly,

lastly, this accumulation of the sensorial power of irritation so far abounds, that it increases the action of the next link of the associated train or tribe of motions; thus on exposing the skin to cold air, as in walking out in a frosty morning, the actions of the stomach are increased, and digestion strengthened.

But where the torpor of some irritative motion is owing to the previous exhaustion of the sensorial power of irritation by too great stimulus, the restoration of it occurs either not at all, or much more slowly than in the former instances; thus after intoxication the stomach is very slow in recovering its due quantity of the sensorial power of irritation, and never shews any accumulation of it.

2. When an affociate motion, as described in the introduction to Class IV. 1. 1. acts with less energy, the sensorial power of affociation is either not fufficiently excited by the preceding fibrous motions; or it has been expended or exhausted by the too violent actions of the preceding fibrous motions. In the former case there occurs an accumulation of the sensorial power of affociation; exactly as, where the usual stimulus is withdrawn, there occurs an accumulation of the fenforial power of irritation. Thus when the actions of the capillaries of the skin are diminished by immersion in cold water, the capillaries of the lungs are rendered torpid by the want of the excitement of the fenforial power of affociation, owing to the leffened actions of the previous fibrous motions, namely, of those of the skin. Nevertheless as foon as the capillaries of the skin regain their increased activity by the accumulation of the fenforial power of irritation, these capillaries of the lungs act with greater energy also owing to their accumulated fenforial power of affociation. These are instances of direct sympathy, and constitute the cold and hot paroxysms of intermittent fever; or the first paroxysm of a continued one.

3. When the first link of a train of affociated motions, which is subject to perpetual action, becomes a considerable time torpid for want of being excited by the previous exertions of the irritative motions, with which it is catenated; the sensorial power of affociation becomes accumulated in so great a degree as to affect the second link of the train of affociated motions, and to excite it into stronger action. Thus when the stomach is rendered torpid by contagious matter swallowed into it mixed with the saliva, the heart and arteries act more seebly; because the sensorial power of affociation, which used to be excited by the sibrous motions of the stomach, is not now excited; and in consequence the motions of the heart and arteries act only by

the fenforial power of irritation, which is excited by the stimulus of the blood.

But during this torpor of the stomach, and less action of the heart and arteries, so great an accumulation of the sensorial powers of irritation and of association occurs, that it adds to the action of the next link of this vital circle of actions, that is, to that of the cutaneous capillaries. Whence in this situation the torpor of the stomach occasions a diminished action of the heart and arteries by direct sympathy, and may be said to occasion an increased one of the cutaneous capillaries by reverse sympathy;

which constitute continued fever with weak pulse.

Nor is this increased action of the capillaries in consequence of the decreased action of the heart and arteries, as in fevers with weak pulse, a single fact in the animal economy; though it exists in this case in the greatest degree or duration, because the heart and arteries are perpetually in greater action than any other part of the fystem. But a similar circumstance occurs, when the stomach is rendered inactive by defective excitement of the fenforial power of affociation, as in fea-fickness, or in nephritis. In these cases the sensorial power of association becomes much accumulated in the stomach, and seems by its superabundance to excite the absorbent system, which is so nearly connected with it, into great increase of action; as is known by the great quantity frequently in these situations rejected by vomit, which could not otherways be supplied. It is probable the increase of digestion by walking in frosty air, with many other animal facts, may by future observations be found to be dependent on this principle, as well as the increased action of the capillaries in continued fevers with weak pulse.

Whereas in continued fever with strong pulse, which may perhaps occur sometimes on the first day even of the plague, the stomach with the heart and arteries and the capillaries act by direct sympathy; that is, the stomach is excited into stronger action by increased irritation owing to the stimulus of contagious matter; these stronger irritative motions of the stomach excite a greater quantity of the sensorial power of affociation, which then actuates the heart and arteries with greater energy, as these are catenated with the stomach; and in the same manner the increased actions of the heart and arteries excite a greater quantity of the sensorial power of affociation, which actuates the cutaneous capillaries with increase of energy. See Class

IV. 1. 1.

4. I shall dwell a little longer on this intricate subject. The commencement of sever-sits is known by the inactivity of the cutaneous capillaries, which inactivity is observable by the pale-

ness and coldness of the skin, and also by the pain of coldness, which attends it. There is nevertheless in most cases, except those which are owing to exposure to external cold, a torpor of the capillaries of some internal viscus preceding this inactivity of the cutaneous capillaries; which is known by the tumour or hardness of the viscus, or by an aching pain of it. The capillaries of the lungs are at the same time rendered inactive or torpid, as appears by the difficulty of breathing, and coldness of the breath in cold sits of sever, and in going into the cold bath; but the lungs are not affected with the pain either of coldness or

of torpor.

One cause of this synchronous or successive inactivity of the cutaneous capillaries, in confequence of the previous torpor of fome internal viscus, may be owing to the deficiency of heat; which must occur, when any part becomes inactive; because the fecretions of that part ceafe or are lessened, and the quantity of heat of it in consequence. But the principal cause of it I fuppose to be owing to the defect of the fenforial power of affociation; which power of affociation is excited by fome previous or concomitant motions of the parts of every great circle of actions. This appears on going into the cold bath, because the shortness of breath instantly occurs, sooner than one can conceive the diminution of the heat of the skin could affect the lungs by the want of its stimulus; but not sooner than the defect of the fenforial power of affociation could affect them; because this must cease to be excited into action on the instant that the cutaneous capillaries cease to act; whence in the first moment of contact of the cold water the cutaneous capillaries cease to act from defect of irritation; which is caused by defect of the stimulus of heat; and in the fecond moment the capillaries of the lungs cease to act from the defect of affociation; which is caused by the defect of the motions of the cutaneous capillaries. Thus the universal torpor in the cold paroxysm of fever is an example of direct sympathy, though occasioned in part by defect of irritation, and in part by defect of affociation.

5. Thus in walking out in a frosty morning the skin is cooled by the contact of the cold air, whence the actions of its capillaries are diminished for want of their usual stimulus of hear to excite a sufficient quantity of the sensorial power of irritation. Hence there is at first a faving of the sensorial power of irritation for the purpose of actuating the other parts of the system with greater energy. Secondly, the sensorial power of association, which used to be excited by the motions of the cutaneous capillaries, is now not so powerfully excited; and in consequence the parts, which constitute the next links of the circles of associations.

ciated

ciated motions, are for a time actuated with lefs energy, and a temporary general chillness succeeds; which is so far similar to the cold fit of intermittent sever.

In this fituation there is a curious circumstance occurs, which merits peculiar attention: after a short time, though the external skin continues cool by its exposure to the cold air, and the actions of its capillaries are consequently diminished, yet the capillaries of the stomach act with greater energy; as is known by increased digestion and consequent hunger. This is to be ascribed to the accumulation of the sensorial power of irritation, which now excites by its superabundance, or overslowing, as it were, the stomach into increased action; though it is at the same time excited less powerfully than usual by the sensorial power of association. Thus the accumulation of the sensorial power of irritation in the vessels of the skin increases in this case the action of the stomach, in the same manner as an accumulation of the sensorial power of association in the heart and arteries in fevers with weak pulse increases the action of the capillaries.

If nevertheless the coldness of the skin be too long continued, or exists in too great a degree, so as in some measure to impair the life of the part, no further accumulation of the sensorial power of irritation occurs; and in consequence the actions of the stomach become less than natural by the defect of the sensorial power of association; which has ceased to be excited by the want of action of the cutaneous capillaries. Whence continued coldness of the section and

heartburn. See Class IV. 2. 1. 6.

6. Similar to this when the actions of the stomach are rendered torpid by the previous stimulus of a violent emetic, and its motions become retrograde in consequence, a great quantity of sensorial power is exerted on the lymphatics of the lungs, and other parts of the body; which excites them into greater direct action, as is evinced by the exhibition of digitalis in anafarca. In this fituation I suppose the emetic drug stimulates the muscular fibres of the stomach into too great action; and that in consequence a great torpor soon succeeds; and that this inaction of the muscular parts of the stomach is not followed by much accumulation of the sensorial power of irritation; because that sensorial power is in great measure exhausted by the previous excessive stimulus. But the lymphatics of the stomach have their actions lessened by defect of sensorial power of affociation, which is not now excited into action, owing to the leffened motions of the muscular parts of it, with which the lymphatics are affociated. The fentorial power of affociation becomes therefore accumulated in these lymphatics of the stom-

Vol. II. M m m ach,

ach, because it is not excited into action; exactly as the power of irritation becomes accumulated in the hand, when immersed in snow; and this accumulated sensorial power of association excites the lymphatics of the lungs and of other parts, which are most nearly associated with those of the stomach, into more energetic actions. Thus the muscular sibres of the stomach act with the lymphatics of that organ in direct sympathy; and the lymphatics of the stomach act in reverse sympathy with those of the lungs and of other parts of the body; the former of which is caused by defect of the excitement of the sensorial power of association, and the latter by the accumulation of it.

Besides the efficient cause, as above explained, the sinal cause, or convenience, of these organic actions are worthy our attention. In this case of an acrid drug swallowed into the stomach the reverted actions of the muscular sibres of the stomach tend to eject its enemy; the reverted actions of its lymphatics pour a great quantity of sluids into the stomach for the purpose of diluting or washing off the noxious drug; and the increased actions of the other lymphatics supply these retrograde ones of the stomach with an inconceivable supply of sluids, as is seen in

Ileus and Cholera.

7. The inquisitive reader will excuse my continuing this subject, though perhaps with some repetitions, as it envelopes the very effence of sever. When the first link of a train of actions is excited by excessive stimulus, or excessive irritability, and thus acts with unusual energy by the increased quantity of irritation, these increased motions excite a greater quantity of the sensorial power of association, which causes increased motions in the second link, which is catenated with the first; and then the excessive action of this second link excites also a greater quantity of the sensorial power of association, which increases the motions of the third link of this chain of association, and thus the increase of the stimulus on the irritative motions, to which the chain of association is catenated, increases the action of the whole chain or circle of associated motions.

After a time the irritative motions become torpid by expenditure of the fenforial power of irritation, and then the power of affociation also becomes less exerted, both because it has been in part exhausted by too great action, and is now less excited by the lessened action of the irritative motions, which used to excite it. These are both instances of direct sympathy, and fre-

quently constitute the cold and hot fit of intermittents.

But though the accumulation of the sensorial power of irritation during the quiescence of some motion owing to want of stimulus generally induces torpor in the first link of the train of associated affociated motions catenated with it; as the capillaries of the lungs become torpid immediately on immersion of the skin into cold water; yet in some situations an orgasm or excess of action is produced in the first link of the affociated motions thus catenated with irritative ones; as in the increased action of the stomach, when the skin is for a time exposed to cold air; which may in part be ascribed to the general increase of action of the whole system, owing to the diminished expenditure of sensorial power, but particularly of the parts, which have habitually acted together; as when one arm is paralytic the other is liable to more frequent or almost continual motion; and when one eye becomes blind the other frequently becomes stronger; which is well known to farriers, who are said sometimes to destroy the sight of one eye to strengthen that of the other in diseased horses.

Hence there is fometimes a direct fympathy, and fometimes a reverse one succeeds the torpor occasioned by defect of stimulus, the latter of which is perhaps owing to a certain time being required for the production of an accumulation of the fenforial power of irritation by the nervous branches of the torpid organ; which accumulation is now in part or entirely derived to the next link of the affociation. Thus in going into a coldish bath, as into a river in the summer months, we at first experience a difficulty of breathing from the torpid action of the pulmonary capillaries, owing to the deficient excitement of the fenforial power of affociation in confequence of the torpor of the cutaneous capillaries. But in a very short time, as in one minute, the fenforial power of irritation becomes accumulated by the inactivity of the cutaneous capillaries; and as its superabundance becomes now expended on the pulmonary capillaries, the difficult respiration ceases; though the cutaneous capillaries continue torpid by their contact with the cold water, and confequently the fenforial power of affociation, which used to contribute to actuate the pulmonary capillaries, is less excited.

8. In like manner when there exists an accumulation of the fensorial power of affociation, owing to defect of its excitement by some previous irritative or affociate motions, it is generally accompanied for a certain time by a torpor not only of the link first affected, but of the subsequent parts, or of the whole train of affociated motions, as in the cold fits of intermittent fevers. Yet after a time an increased action of the next links of affociated motions succeeds the torpor of the first, as the absorbent vessels of the lungs act more violently in consequence of the deficient action of those of the stomach; and the skin at the commencement of sickness is pale and cold, but in a little time be-

comes flushed and warm.

Thus we fee in affociate motions, which are rendered torpid by defect of excitement, that sometimes a direct, and sometimes a reverse sympathy succeeds in the subsequent links of the chain. But I believe where a torpor of irritative or of the affociate motions is caused by a previous too great expenditure or exhaustion of the sensorial powers of irritation or association, no increase of action in the subsequent link ever occurs, or not till after a

very long time.

Thus when the stomach becomes torpid by previous violent exertion, and confequent exhaustion of the sensorial power of irritation, as after intoxication with wine or opium, or after the exhibition of fome violent emetic drug, the torpor is communicated to the heart and arteries, as in continued fevers with weak pulse. But where the torpor of the stomach is produced from defective affociation, as in fea-fickness; or in the fickness which occurs, when a stone stimulates the ureter; no torpor is then communicated to the heart and arteries. For in the former case there is no accumulation of sensorial power in the stomach, which was previously exhausted by too great stimulus; but in the latter case the accumulation of sensorial power in the stomach during its torpor is evinced by this circumstance; that in fea-fickness the patients eat and drink voraciously at intervals; and the pulse is generally not affected by the sickness occasioned by a stone in the ureter. For the action of the stomach is then leffened, and in confequence becomes retrograde; not owing to the exhaustion of the sensorial power of irritation, but to the want of excitement of the fenforial power of affociation; which is caused by the defective action of the ureter, which becomes occasionally torpid by the great stimulus of the stone it contains; or which is caused by the great exhaustion of sensorial power by the pain; which affects the ureter without exciting inflammation, or increased action of it.

9. Thus though the stomach after the great stimulus of intoxication from excess of wine or opium will continue many hours without accumulation of sensorial power, as appears from the patient's experiencing no appetite at the intervals of sickeness; yet after long abstinence from food, at length not only the exhausted quantity of sensorial power is renewed, but an accumulation of it at length occurs, and hungerreturns. In this situation the stomach is generally about a whole day before it regains its usual powers of digestion; but if it has been still more violently stimulated, and its actions surther impaired, a still more permanent terpor, along with a continued fever with weak pulse is liable to occur; and a fourth part, or a half, or three-fourths, or a

whole lunar period passes, before it recovers its due irritability

and confequent action.

In fimilar manner, after a person has been confined in a very warm room for some hours, the cutaneous capillaries, with their secretory and absorbent vessels, become exhausted of their sensorial power of irritation by the too great violent exertions occafioned by the unusual stimulus of heat; and in coming into a colder atmosphere an inactivity of the cutaneous vessels exists at first for some time without accumulation of sensorial power; as is shewn by the continuance of the pain of cold and the paleness; but after a time both the pain of cold and paleness vanish, which now indicates an accumulation of the sensorial power of irritation, as less degrees of heat stimulate the system into due action.

In the fame manner, after any one has been fome time in the fummer funshine, on coming into a dark cell he continues much longer before he can clearly distinguish objects, than if his eyes had only been previously exposed to the light of a cloudy day in winter; because the sensorial power of irritation, and consequent sensation, had in the first case been previously much expended or exhausted; and therefore required a much longer time before it could be produced in the brain, or derived to the optic nerves, in such quantity as to restore the desiciency, and to cause an accumulation of it; whereas in the latter case no desiciency had occurred.

10. Thus the accumulation or deficiency of fenforial power in a torpid organ, which had previously been accustomed to perpetual action, depends on the manner in which it becomes torpid; that is, whether by great previous stimulus, or great previous excitement of the power of affociation; or by defect of its accustomed stimulus, or of its accustomed excitement of the power of affociation. In the former case the sensor is in an exhausted state, and therefore is not likely to become so soon accumulated, as after drunkenness, or exposure to great heat, or to great light; in the latter a great accumulation of sensorial power occurs, as after exposure to cold, or hunger, or darkness.

Hence when the stomach continues torpid by previous violent stimulus, as in the exhibition of digitalis, no accumulation of sensorial power of irritation supervenes; and in consequence the motions of the heart and arteries, which are associated with those of the stomach, become weak, and slow, and intermittent, from the defect of the excitement of the sensorial power of association. But what sollows? as the actions of the heart and arteries are lessened by the deficient action of the sensorial power of association, and not by previous increased excitement of it; a great accumulation of the fenforial power of affociation occurs, which is exerted on the pulmonary and cutaneous absorbents by reverse sympathy, and produces a great absorption of the fluid effused into the cellular membrane in anasarca, with

dry skin; constituting one kind of atrophy.

But if at the same time the secerning vessels of the stomach are stimulated into so violent activity as to induce great confequent torpor, as probably happens when contagious matter is swallowed into the stomach with our faliva, those of the heart and arteries act feebly from the deficient excitement of the power of affociation; and then the cutaneous and pulmonary fecerning veffels act with greater force than natural, owing to the accumulation of the fenforial power of affociation; and unnatural heat of the skin, and of the breath succeed; but without frequency of pulse, constituting the paresis irritativa of Class I. 2. 1. 2. And lastly, if a paucity of blood attends this paresis or fome other cause inducing a frequency of pulse, the febris inirritativa, or fever with weak pulse, is produced.

But on the contrary when the stomach has previously been rendered torpid by defect of stimulus, as by hunger, if food be too haftily supplied, not only great exertion of the stomach itfelf fucceeds, but fever with strong pulse is induced in confequence; that is, the heart and arteries are excited into more energetic action by the excels of the power of affociation, which catenates their motions with those of the stomach. For the redundancy of fenforial power of irritation, which was accumulated during the inactivity of the stomach, and is now called into action by stimulus, actuates that organ with increased energy, and excites by these increased motions the sensorial power of affociation; which has also been accumulated during the inactivity of the heart and arteries; and thus these organs also are now excited into greater action.

So after the skin has been exposed some hours to greater heat than natural in the warm room, other parts as the membranes of the nostrils, or of the lungs, or of the stomach, are liable to become torpid from direct sympathy with it, when we come into air of a moderate temperature; whence catarrhs, coughs, and fevers. But if this torpor be occasioned by defect of stimlus, as after being exposed to frosty air, the accumulation of fenforial power is exerted, and a glow of the skin follows, with increased digestion, full respiration, and more vigorous circu-

lation.

11. It may be asked, Why is there a great and constant accumulation of the fenforial power of affociation, owing to the torpor of the stomach and heart and arteries, in continued fever with

with weak pulse; which is exerted on the cutaneous and pulmonary capillaries, fo as to excite them into increased action for many weeks, and yet no fuch exuberance of fenforial power produces fever in winter-fleeping animals, or in chlorofis, or apepfia, or hysteria?

In winter-fleeping animals I suppose the whole nervous system is torpid, or paralysed, as in the sleep of frozen people; and that the stomach is torpid in consequence of the inactivity or quiescence of the brain; and that all other parts of the body, and the cutaneous capillaries with the rest, labour under a sim-

In chlorofis, I imagine, the actions of the heart and arteries, as well as those of the cutaneous and pulmonary capillaries, suffer along with those of the stomach from the deficient stimulus of the pale blood; and that though the liver is probably the feat of the original torpor in this difease, with which all other parts sympathize from defect of the excitation of the fenforial power of affociation; yet as this torpor occurs in fo small a degree as not to excite a shuddering or cold fit, no observable consequences are in general occasioned by the consequent accumulation of sensorial power. Sometimes indeed in chlorofis there does occur a frequent pulse and hot skin; in which circumstances I suppose the heart and arteries are become in some degree torpid by direct sympathy with the torpid liver; and that hence not only the pulse becomes frequent, but the capillaries of the skin act more violently by reverse sympathy with the heart and arteries, owing to the accumulation of the fenforial power of affociation in them during their torpid state, as occurs in irritative fever. See Article 11. of this Supplement.

In apeplia chronica the actions of the stomach are not so far impaired or destroyed as totally to prevent the excitation of the fenforial power of affociation, which therefore contributes fomething towards the actions of the heart and arteries, though less than natural, as a weak pulse always I believe attends this dif-

eafe.

There is a torpor of the stomach, and of the upper part of the alimentary canal in hysteria, as is evident from the retrograde actions of the duodenum, stomach, and cesophagus, which constitute the globus hystericus, or sensation of a globe rising into the throat. But as these retrograde actions are less than those, which induce fickness or vomiting, and are not occasioned by previous exhaustion of the sensorial power of irritation, they do not so totally prevent the excitement of the fenforial power of affociation, as to leffen the motion of the heart and arteries fo much as to induce fever; yet in this case, as in apepsia, and in cholorofis,

chlorosis, the pulsations of the heart and arteries are weaker than natural, and are sometimes attended with occasionally increased action of the capillaries; as appears from the slushings of the sace, and hot skin, which generally form an evening febricula in

diseases attended with weak digestion.

12. The increased action, or orgasm, of the cutaneous, pulmonary, and cellular capillaries, with their fecerning and abforbent vessels, in those fevers which are attended with deficiency of vital action, exhausts the patient both by the additional expenditure of fenforial power on those organs of secretion, and by the too great absorption of the mucus and fat of the body; whence great debility and great emaciation. Hence one great indication of cure of continued fever with arterial debility is to diminish the too great action of the capillaries; which is to be done by frequent ablutions, or bathing the whole skin in tepid or in cold water, as recommended by Dr. Currie of Liverpool (Philof. Trans. for 1792), for half an hour, twice a day, or at those times when the skin feels dryest and hottest. Much cool air should also be admitted, when the breath of the patient feels hot to one's hand; or when the tongue, especially its middle part, is dry, and covered with a crust of indurated mucus; as these indicate the increased action of the pulmonary capillaries; in the same manner as the dry and hot skin indicates the orgasm of the cutaneous capillaries; and the emaciation of the body that of the cellular ones.

For this purpose of abating the action of the capillaries by frequent ablution or fomentation, water of any degree of heat beneath that of the body will be of service, and ought in accurate language to be called a cold bath; but the degree of coldness, where the patient is sensible, should in some measure be governed by his sensations; as it is probable, that the degree of coldness, which is most grateful to him, will also be of the greatest benefit to him. See Class III. 2. 1. 12. and Article 15. of this Supplement.

Another great use of frequent ablutions, or fomentations, or baths, in fevers, where the stomach is in some degree torpid, is to supply the system with aqueous sluid by means of the cutaneous absorbents; which is dissipated faster by the increased action of the secerning capillaries, than the stomach can furnish,

and occasions great thirst at the intervals of the sickness.

IX. Torpor of the Lungs.

1. The lungs in many cases of contagion may first be affected with torpor, and the skin become cold by sympathy; in the

fame manner as a cold skin on going into the cold bath induces difficulty of breathing. Or the stomach may become affected with torpor by its sympathy with the lungs, as in the experiments of Mr. Watt with hydrocarbonate gas; a few respirations of which induced sickness, and even syncope. When the stomach or skin is thus affected secondarily by association, an accumulation of sensorial power occurs much sooner, than when these parts become torpid in consequence of previous excess of stimulus; and hence they sooner recover their accustomed action, and the sever ceases. The particles of contagious matter thus received by respiration somewhat resemble in their effects the acid gases from burning sulphur, or from charcoal; which, if they do not instantly destroy, induce a sever, and the patient slowly recovers.

2. I was some years ago stooping down to look, which way the water oozed from a moras, as a labourer opened it with a spade, to detect the source of the spring, and inhaled a vapour, which occasioned an instant sense of suffocation. Immediately recoiling I believe I inhaled it but once; yet a few hours afterwards in the cool of the evening, when I returned home rather satigued and hungry, a shivering and cold sit occurred, which was followed by a hot one; and the whole disease began and terminated in about twelve hours without return. In this case the power of fear, or of imagination, was not concerned; as I neither thought of the bad air of a morass before I perceived it;

nor expected a fever-fit, till it occurred.

In this case the torpor commenced in the lungs, and after a few hours, by the addition of fatigue, and cold, and hunger, was propagated by direct sympathy to the rest of the system. An orgasm or increased action of the whole system was then induced by the accumulation of fenforial power of irritation in the lungs, and of affociation in the other organs; and when these subsided, the disease ceased. It may be asked, could a torpor of the capillaries of the air-vessels of the lungs be so suddenly produced by great stimulation?-It appears probable, that it might, because great exertion of irritative motions may be instantly produced without our perceiving them; that is, without their being attended by fenfation, both in the lungs and stomach; and the organs may become torpid by the great expenditure of the fenforial power of itritation in an instant of time; as paralysis frequently instantly follows too great an exertion of voluntary power.

3. When the capillaries of the lungs act too violently, as in fome continued fevers; which is known by the heat of the breath, and by the dryness of the tongue, especially of the mid-

dle part of it; not only cooler air might be admitted more freely into a fick room to counteract this orgasm of the pulmonary capillaries; but perhaps the patient might breathe with advantage a mixture of carbonic acid gas, or of hydrogene gas, or of azote with atmospheric air. And on the contrary, when there exists an evident torpor of the pulmonary capillaries, which may be known by the correspondent chillness of the skin; and by a tickling cough, which sometimes attends cold paroxysms of sever, and is then owing to the desicient absorption of the pulmonary mucus, the faline parts of which stimulate the bronchia, or air-vessels; a mixture of one part of oxygen gas with 10 or 20 parts of atmospheric air might probably be breathed with great advantage.

X. Torpor of the Brain.

As the inactivity or torpor of the abforbent veffels of the brain is the caufe of hydrocephalus internus; and as the deficiency of venous abforption in the brain, or torpor of the extremities of its veins, is believed frequently to be the caufe of apoplexies; fo there is reason to conclude, that the torpor of the fecerning veffels of the brain, which are supposed to produce the sensorial power, may constitute the immediate cause of some fevers with arterial debility. And also that the increased action of these secreting vessels may sometimes constitute the immediate cause of severs with arterial strength.

It is neverthelefs probable, that the torpor or orgafm of the fanguiferous, abforbent, or fecerning veffels of the brain, may frequently exist as a fecondary effect, owing to their affociation with other organs, as the stomach or lungs; and may thus be produced like the torpor of the heart and arteries in inirritative fevers, or like the orgafm of those organs in irritative fevers, or

inflammatory ones.

Where there exists a torpor of the brain, might not very slight electric shocks passed frequently through it in all directions be used with advantage? Might not somentations of 94 or 96 degrees of heat on the head for an hour at a time, and frequently repeated, stimulate the brain into action; as in the revival of winter-sleeping animals by warmth? Ether externally might be frequently applied, and a blister on the shaved head.

Where the fecerning vessels of the brain act with too great energy, as in some inflammatory fevers, might it not be diminished by laying the patient horizontally on a mill-stone, and whirling him, till sleep should be produced, as the brain becomes compressed by the centrifugal force? See Article 15. of this Supplement.

XI. Torpor of the Heart and Arteries.

1. It was shewn in Class IV. 1. 1. 6. in IV. 2. 1. 2. and in Suppl. I. 6. 3. that a reverse sympathy generally exists between the lacteal and lymphatic branches of the absorbent system. Hence, when the motions of the absorbents of the stomach are rendered torpid or retrograde in severs with arterial debility, those of the skin, lungs, and cellular membrane, act with increased energy. But the actions of the muscular sibres of the heart and arteries are at the same time associated with those of the muscular sibres of the stomach by direct sympathy. Both these actions occur during the operation of powerful emetics, as squill, or digitalis; while the motions of the stomach continue torpid or retrograde, the cellular and cutaneous absorbents act with greater energy, and the pulsations of the heart and arteries become weaker, and sometimes slower.

2. The increased action of the stomach after a meal, and of the heart and arteries at the same time from the stimulus of the new supply of chyle, seems originally to have produced, and to have established this direct sympathy between them. As the increased action of the absorbents of the stomach after a meal has been usually attended with diminished action of the other branches of the absorbent system, as mentioned in Class IV. 1. 1. 6. and has thus established a reverse sympathy between

them.

2. Besides the reverse sympathy of the absorbent vessels and the muscles of the stomach, and of the heart and arteries, with those of the skin, lungs, and cellular membrane; there exists a similar reverse sympathy between the secerning vessels or glands of the former of these organs with those of the latter; that is the mucous glands of the heart and arteries act generally by direct sympathy with those of the stomach; and the mucous glands of the cellular membrane of the lungs, and of the skin, act by reverse sympathy with them both.

Hence when the stomach is torpid, as in sickness, this torpor fometimes only affects the absorbent vessels of it; and then the absorbents of the cellular membrane and the skin only act with increased energy by reverse sympathy. If the torpor affects the muscular fibres of the stomach, those of the heart and arteries act by direct sympathy with it, and a weak pulse is produced, as in the exhibition of digitalis, but without increase of heat. But if the torpor also affects the glands of the stomach, the cu-

taneous and pulmonary glands act with greater energy by their reverse sympathy with those of the stomach, and of the heart and arteries; and great heat is produced along with increased

perspiration both from the skin and lungs.

3. There is some difficulty in explaining, why the actions of the extensive system of capillary glands, which exist on every other membrane and cell in the body for the purpose of secreting mucus and perspirable matter, should so generally act by reverse sympathy with those of the stomach and upper part of the intestines. It was shewn in Class IV. 1. 1. 6. that when the stomach was filled with solid and fluid aliment, the absorbents of the cellular membrane, and of the bladder, and of the skin, acted with less energy; as the sluids, they were used to absorb and transmit into the circulation, were now less wanted; and that hence by habit a reverse sympathy obtained between these branches of the absorbents of the alimentary canal, and those of the other parts of the body.

Now, as at this time lefs fluid was absorbed by the cutaneous and cellular lymphatics, it would happen, that lefs would be fecreted by their correspondent fecerning vessels, or capillary glands; and that hence by habit, these secenting vessels would acquire a reverse sympathy of action with the secerning vessels

of the alimentary canal.

Thus when the absorption of the tears by the puncta lacrymalia is much increased by the stimulus of snuff; or of an affecting idea, on the nasal ducts, as explained in Sect. XVI. 8. 2. a great increase of the secretion of tears from the lacrymal glands is produced by the direct sympathy of the action of these glands with those of their correspondent absorbents; and that though in this case they are placed at so great a distance from each other.

4. A difficult question here occurs; why does it happen, that in fevers with weak pulse the contractions of the heart and arteries become at the same time more frequent; which also sometimes occurs in chlorosis, and in some hysteric and hypochondriac diseases, and in some infanities; yet at other times the weak pulse becomes at the same time slow, as in the exhibition of digitalis, and in paresis irritativa, described in Class I. 2. 1. 2. which may be termed a fever with slow pulse? this frequency of pulse cannot depend on heat, because it sometimes exists without heat, as towards the end of some fevers with debility.

Now as apoplexies, which are fometimes ascribed to fulness of blood, are attended with flow pulse; and as in animals dying in the slaughter-house from deficiency of blood the pulse becomes frequent in extreme; may not the frequency of pulse in

fevers

fevers with arterial debility be in general owing to paucity of blood? as explained in Sect. XXXII. 2. 3. and its flowness in parefis irritativa be caused by the debility being accompanied with due quantity of blood? or may not the former circumstance sometimes depend on a concomitant affection of the brain approaching to fleep? or to the unufual facility of the passage of the blood through the pulmonary and aortal capillaries? in which circumstance the heart may completely empty itself at each pulsation, though its contractions may be weak. While the latter depends on the difficulty of the paffage of the blood through the pulmonary or aortal capillaries, as in the cold fits of intermittents, and in some palpitations of the heart, and in fome kinds of hæmoptoe; in these cases the increased resistance prevents the heart from emptying itself, and in consequence a new diastole sooner occurs, and thus the number of pullations becomes greater in a given time.

5. In respect to the sympathies of action, which produce or constitute fever with debility, the system may be divided into certain provinces, which are effentient or opposite to each other. First, the lacteals or absorbent vessels of the stomach, and upper part of the intestines; secondly, the lymphatics or all the other branches of the absorbent vessels, which arise from the skin, mucous membranes, cellular membranes, and the various glands. These two divisions act by reverse sympathy with each other in the hot fits of fever with debility, though by direct fympathy in the cold ones. The third division confifts of the fecerning vessels of the stomach and upper intestines; and the fourth of the fecerning veffels of all the other parts of the body, as the capillary glands of the skin, lungs, and cellular membrane, and the various other glands belonging to the fanguiferous tyl-Many of these frequently, but the capillaries always, act by reverse sympathy with those of the third division above mentioned in the hot fits of fever with debility, though by direct fympathy with them in the cold fits. Fifthly, the muscular fibres of the stomach, and upper intestines; and fixthly, the muscular fibres of the heart and arteries. The actions of thefe two last divisions of moving fibres act by direct sympathy with each other, both in the cold and hot fits of fevers with debility.

The efficient cause of those apparent sympathies in severs with weak pulse may be thus understood. In the cold paroxysm of sever with weak pulse the part first affected I believe to be the stomach, and that it has become torpid by previous violent exertion, as by swallowing contagious matter mixed with saliva, and not by desect of stimulus, as from cold or hunger. The actions of this important organ, which sympathizes with almost

every part of the body, being thus much diminished or nearly destroyed, the sensorial power of association is not excited; which in health contributes to move the heart and arteries, and all the rest of the system; whence an universal torpor occurs.

When the hot fit approaches, the stomach in fevers with strong pulse regains its activity by the accumulation of the sen-sorial power either of irritation, if it was the part first affected, or of affociation if it was affected in sympathy with some other torpid part, as the spleen or liver; which accumulation is produced during its torpor. At the same time all the other parts of the system acquire greater energy of action by the accumulation of the sensorial power of affociation, which was produced,

during their inactivity in the cold fit.

But in fevers with weak pulse the stomach, in which the fenforial power of irritation had been previously exhausted by violent action, acquires no fuch quick accumulation of fenforial power, but remains in a state of torpor after the hot fit commences. The heart and arteries remain also in a state of torpor, because there continues to be no excitement of their power of affociation owing to the torpid motions of the stomach; but hence it happens, that there exists at this time a great accumulation of the power of affociation in the lefs active fibres of the heart and arteries; which, as it is not excited and expended by them, increases the affociability of the next link of the affociated chain of motions, which confifts of the capillaries or other glands; and that in fo great a degree as to actuate them with unnatural energy, and thus to produce a perpetual hot fit of fever. Because the affociability of the capillaries is so much increafed by the accumulation of this power, owing to the leffened activity of the heart and arteries, as to over-balance the leffened excitement of it by the weaker movements of the heart and arteries.

6. When the accumulation of the fenforial power of irritation caused by defect of stimulus is greater in the first link of a train of actions, to which associated motions are catenated, than the deficiency of the excitement of the sensorial power of association in the next link, what happens?—the superabundance of the unemployed sensorial power of the first link is derived to the second; the association by which thus becomes so greatly increased, that it acts more violently than natural, though the excitement of its power of association by the lessened action of the first link is less than natural. So that in this situation the withdrawing of an accustomed stimulus in some parts of the system will decrease the irritative motions of that part, and at the same

time

time occasion an increase of the affociate motion of another part, which is catenated with it.

This circumstance nevertheless can only occur in those parts of the fystem, whose natural actions are perpetual, and the accumulation of sensorial power on that account very great, when their activity is much lessened by the deduction of their usual stimulus; and are therefore only to be found in the sanguiserous system, or in the alimentary canal, or in the glands and capillaries. Of the first of which the following is an instance.

The respiration of a reduced atmosphere, that is of air mixed with hydrogene or azote, quickens the pulse, as observed in the case of Mrs. Eaton by Dr. Reynolds and Dr. Thornton; to which Dr. Beddoes adds in a note, that "he never saw an instance in which a lowered atmosphere did not at the moment quicken the pulse, while it weakened the action of the heart and arteries." Considerations on Factitious Airs, by Thomas Beddoes and James Watt, Part III. p. 67. Johnson, London. By the affistance of this new fact the curious circumstance of the quick production of warmth of the skin on covering the head under the bed-clothes, which every one must at some time have experienced, receives a more satisfactory explanation, than that which is given in Class IV. 1. 1. 2. which was printed before this part of Dr. Beddoes's Considerations was published.

For if the blood be deprived of its accustomed quantity of oxygen, as in covering the head in bed, and thus breathing an air rendered impure by repeated respiration, or by breathing a factitious air with less proportion of oxygen, which in common respiration passes through the moist membranes of the lungs, and mixes with the blood, the pulsations of the heart and arteries become weaker, and consequently quicker, by the defect of the stimulus of oxygen. And as these vessels are subject to perpetual motion, the accumulation of the sensorial power of irritation becomes so great by their lessened activity, that it excites the vessels next connected, the cutaneous capillaries for instance, into more energetic actions, so as to produce increased heat of the skin, and greater perspiration.

How exactly this refembles a continued fever with weak and quick pulse!—in the latter the action of the heart and arteries are lessened by defect of the excitement of the sensorial power of association, owing to the torpor or lessened actions of the stomach; hence the accumulation of the sensorial power of association in this case, as the accumulation of that of irritation in the former, becomes so abundant as to excite into increased action the parts most nearly connected, as the cutaneous capillaries.

In respect to the circumstance mentioned by Sydenham, that

covering

covering the head in bed in a short time relieved the pertinacious sickness of the patient, it must be observed, that when the action of the heart and arteries becomes weakened by the want of the due stimulus of the proper quantity of oxygen in the blood, an accumulation of the sensorial power of irritation occurs in the fibres of the heart and arteries, which then is expended on those of the capillary glands, increasing their actions and consequent secretions and heat. And then the stomach is thrown into stronger action, both by the greater excitement of its natural quantity of the sensorial power of association by the increased actions of the capillaries, and also by some increase of associations, as it had been previously a long time in a state of torpor, or less activity than natural, as evinced by its perpetual sickness.

In a manner somewhat similar to this, is the redness of the skin produced in angry people by the superabundance of the unemployed seusorial power of volition, as explained in Class IV. 2. 3. 5. Rubor ex irâ. From hence we learn how, when people in severs with weak pulse, or in dropsies, become infane, the abundance of the unemployed sensorial power of volition increases the actions of the whole moving system, and cures those diseases.

7. As the orgasm of the capillaries in severs with weak pulse is immediately caused by the torpid actions of the heart and arteries, as above explained, this supplies us with another indication of cure in such severs, and that is to stimulate these organs. This may probably be done by some kind of medicines, which are known to pass into the blood unchanged in some of their properties. It is possible that nitre, or its acid, may pass into the blood and increase the colour of it, and thus increase its stimulus, and the same may be supposed of other salts, neutral or metalic? As rubia tinctoria, madder, colours the bones of young animals, it must pass into the blood with its colouring matter at least unchanged, and perhaps many other medicines may likewise affect the blood, and thus act by stimulating the heart and arteries, as well as by stimulating the stomach; which circumstance deferves surther attention.

Another way of immediately stimulating the heart and arteries would be by transfusing new blood into them. Is it possible that any other study besides blood, as chyle, or milk, or water, could, if managed with great art, be introduced safely or advantageously into the vein of a living animal?

A third method of exciting the heart and arteries immediately is by increasing the natural stimulus of the blood, and is well worthy experiment in all severs with weak pulse; and that con-

sists in supplying the blood with a greater proportion of oxygen; which may be done by respiration, if the patient was to breathe either oxygen gas pure, or diluted with atmospheric air, which might be given to many gallons frequently in a day, and by passing through the moist membranes of the lungs, according to the experiments of Dr. Priestley, and uniting with the blood, might render it more stimulant, and thus excite the heart and arteries into greater action! May not some easier method of exhibiting oxygen gas by respiration be discovered, as by using very small quantities of hyper-oxygenated marine acid gas very much diluted with atmospheric air?

XII. Torpor of the Stomach and upper Intestines.

t. The principal circumstance, which supports the increased action of the capillaries in continued fever with weak pulse, is their reverse sympathy with those of the stomach and upper intestines, or with those of the heart and arteries. The torpor of the stomach and upper intestines is apparent in continued severs from the total want of appetite for solid food, beside the sickness with which severs generally commence, and the frequent diarrhoea with indigested stools, at the same time the thirst of the patient is sometimes urgent at the intervals of the sickness. Why the stomach can at this time take sluids by intervals, and not solids, is difficult to explain; except it be supposed, as some have affirmed, that the lacteal absorbents are a different branch from the lymphatic absorbents, and that in this case the former only are in a state of permanent torpor.

2. The torpor of the heart and arteries is known by the weakness of the pulse. When the actions of the absorbents of the stomach are diminished by the exhibition of small doses of digitalis, or become retrograde by larger ones, the heart and arteries act more feebly by direct sympathy; but the cellular, cutaneous, and pulmonary absorbents are excited into greater action. Whence in anasarca the fluids in the cellular membrane throughout the whole body are absorbed during the sickness, and frequently a great quantity of atmospheric moisture at the same time; as appears by the very great discharge of urine, which sometimes happens in these cases; and in ileus the prodigious evacuations by vomiting, which are often a hundred fold greater than the quantity swallowed, evince the great action of all the other absorbents during the sickness of the stomach.

3. But when the stomach is rendered permanently sick by an emetic drug, as by digitalis, it is not probable, that much accumulation of sensorial power is soon produced in this organ;

Vol. II.

because its usual quantity of sensorial power is previously exhausted by the great stimulus of the foxglove; and hence it feems probable, that the great accumulation of fenforial power, which now causes the increased action of the absorbents, is produced in confequence of the inactivity of the heart and arteries; which inactivity is induced by deficient excitement of the fenforial power of affociation between those organs and the stomach, and not by any previous exhaustion of their natural quantity of sensorial power; whereas in ileus, where the torpor of the stomach, and consequent sickness, is induced by reverse sympathy with an inflamed intestine, that is, by differened or defective affociation; the accumulation of fenforial power, which in that difease so violently actuates the cellular, pulmonary, and cutaneous absorbents, is apparently produced by the torpor of the stomach and lacteals, and the consequent accumulation of the fenforial power of affociation in them owing to their leffened action in fickness.

4. This accounts for the dry skin in fevers with weak pulse, where the stomach and the heart and arteries are in a torpid state, and for the sudden emaciation of the body; because the actions of the cellular and cutaneous absorbents are increased by reverse sympathy with those of the stomach, or with those of the heart and arteries; that is by the expenditure of that sensorial power of affociation, which is accumulated in consequence of the torpor of the stomach and heart and arteries, or of either of them; this also explains the sudden absorption of the milk in puerperal severs; and contributes along with the heat of the respired air to the dryness of the mucous membrane of the

tongue and nostrils.

5. Besides the reverse sympathy, with which the absorbent vessels of the stomach and upper intestines act in respect to all the other absorbent vessels, as in the exhibition of digitalis, and in ileus; there is another reverse sympathy exists between the capillaries, or secretory vessels of the stomach, and those of the skin. Which may nevertheless be occasioned by the accumulation of sensorial power by the torpor of the heart and arteries, which is induced by direct sympathy with the stomach; thus when the torpor of the stomach remains in a sever-fit, which might otherwise have intermitted, the torpor of the heart and arteries remains also by direct sympathy, and the increased cutaneous capillary action, and consequent heat, are produced by reverse sympathy; and the sever is thus rendered continual, owing primarily to the torpor of the stomach.

6. The reverse sympathy, which exists between the capillaries of the stomach and the cutaneous capillaries, appears by the

chillness

chillness of some people after dinner; and contrariwise by the digestion being strengthened, when the skin is exposed to cold air for a short time; as mentioned in Class IV. 1. 1. 4. and IV. 2. 1. 1. and from the heat and glow on the skin, which attends the action of vomiting; for though when sickness first commences, the skin is pale and cold; as it then partakes of the general torpor, which induces the sickness; yet after the vomiting has continued some minutes, so that an accumulation of sensorial power exists in the capillaries of the stomach, and of the skin, owing to their diminished action; a glow of the skin succeeds, with sweat, as well as with increased absorption.

7. Nevertheless in some circumstances the stomach and the heart and arteries seem to act by direct sympathy with the cutaneous capillaries, as in the slushing of the face and glow of the skin of some people after dinner; and as in severs with strong pulse. In these cases there appears to be an increased production of sensorial power, either of sensation, as in the blush of shame; or of volition, as in the blush of anger; or of irritation,

as in the flushed face after dinner above mentioned.

This increased action of the capillaries of the skin along with the increased actions of the stomach and heart is perhaps to be esteemed a synchronous incrase of action, rather than a sympathy between those organs. Thus the slushing of the sace after dinner may be owing to the secretion of sensorial power in the brain being increased by the association of that organ with the stomach, in a greater proportion than the increased expenditure of it, or may be owing also to the stimulus of new chyle received into the blood.

8. When the stomach and the heart and arteries are rendered torpid in fevers, not only the cutaneous, cellular, and pulmonary absorbents are excited to act with greater energy; but also their correspondent capillaries and secerning vessels or glands, especially perhaps those of the skin, are induced into more energetic action. Whence greater heat, a greater fecretion of perspirable matter, and of mucus; and a greater absorption of them both, and of aerial moisture. These reverse sympathies coincide with other animal facts, as in eruption of small-pox on the face and neck the feet become cold, while the face and neck are much flushed; and in the hemiplegia, when one arm and leg become disobedient to volition, the patient is perpetually moving the other. Which are well accounted for by the accumulation of fenforial power in one part of an affociated feries of actions, when less of it is expended by another part of it; and by a deficiency of tenforial power in the fecond link of affociation, when too much of it is expended by the first.

9. This

o. This doctrine of reverse sympathy enables us to account for that difficult problem, why in continued fevers the increased action of the cutaneous, cellular, and pulmonary capillaries proceeds without interruption or return of cold fit; though perhaps with some exacerbations and remissions; and that during a quarter, or half, or three quarters, or a whole lunation; while at the same time the pulsations of the heart and arteries are weaker than natural.

To this should be added the direct sympathy, which exists between the peristaltic motions of the fibres of the stomach, and the pulsations of the heart. And that the stomach has become torpid by the too great stimulus of some poisonous or contagious matter; and this very intricate idea of continued fever with fee-

ble pulse is reduced to curious simplicity.

The direct sympathy of the stomach and heart and arteries not only appears from the itronger and flower pulse of persons exhausted by fatigue, after they have drunk a glass of wine, and eaten a few mouthfuls; but appears also from the exhibition of large doses of digitalis; when the patient labours under great and incessant efforts to vomit, at the same time that the actions of the absorbent system are known to be much increased by the hasty absorption of the serous fluid in anasarca, the pulsations of the heart become flow and intermittent to an alarming degree. See Class IV. 2. 1. 17. and 18.

10. It would assist us much in the knowledge and cure of fevers, if we could always determine, which part of the fystem was primarily affected; and whether the torpor of it was from previous excess or defect of stimulus; which the industry of future observers must discover. Thus if the stomach be affected primarily, and that by previous excess of stimulus, as when certain quantities of opium, or wine, or blue vitriol, or arfenic, are fwallowed, it is some time in recovering the quantity of sensorial power previously exhausted by excess of stimulus, before any accumulation of it can occur. But if it be affected with torpor secondarily, by sympathy with some distant part; as with the torpid capillaries of the skin, that is by defective excitement of the fenforial power of affociation; or if it be affected by defect of stimulus of food or of heat; it sooner acquires so much accumulation of fenforial power, as to be enabled to accommodate itself to its lessened stimulus by increase of its irritability.

Thus in the hemicrania the torpor generally commences in a difeased tooth, and the membranes about the temple, and also those of the stomach become torpid by direct synchronous sympathy; and pain of the head, and fickness supervene; but no fever or quickness of pulse. In this case the torpor of the stomach is owing to defect of the fenforial power of affociation, which is caused by the too feeble actions of the membranes surrounding the diseased tooth, and thus the train of sympathy ceases here without affecting the motions of the heart and arteries; but where contagious matter is swallowed into the stomach, the stomach after a time becomes torpid from exhaustion of the senforial power of irritation, and the heart and arteries act feebly from defect of the excitement of the power of association. In the former case the torpor of the stomach is conquered by accumulation of the power of association in one or two whole days; in the latter it recovers by accumulation of the power of irritation in three or four weeks.

In intermittent fevers the stomach is generally I believe affected secondarily by sympathy with the torpid cutaneous capillaries, or with some internal torpid viscus, and on this account an accumulation of sensorial power arises in a few hours sufficient to restore the natural irritability of this organ; and hence the hot sit succeeds, and the sever intermits. Or if this accumulation of sensorial power becomes excessive and permanent, the continued sever with strong pulse is produced, or febris irritativa.

In continued fevers the stomach is frequently I suppose affected with torpor by previous excess of stimulus, and consequent exhaustion of sensorial power, as when contagious matter is swallowed with the saliva, and it is then much slower in producing an accumulation of sensorial power sufficient to restore its healthy irritability; which is a frequent cause of continued sever with weak pulse or febris inirritativa. Which consists, after the cold sit is over, in a more frequent and more feeble action of the heart and arteries, owing to their direct sympathy with the muscular sibres of the torpid stomach; together with an increased action of the capillaries, glands, and absorbents of the skin, and cellulular membrane, owing to their reverse sympathy with the torpid capillaries, glands, and absorbents of the stomach, or with those of the heart and arteries.

Or in more accurate language. 1. The febris inirritativa, or fever with weak pulse, commences with torpor of the stomach, occasioned by previous exhaustion of sensorial power of irritation by the stimulus of contagious matter swallowed with the saliva. 2. The whole system becomes torpid from defect of the excitement of the sensorial power of association owing to the too feeble actions of the stomach, this is the cold fit. 3. The whole system, except the stomach with the upper intestines, and the heart and arteries, falls into increased action, or orgasm, owing to accumulation of sensorial power of association during

their

Fifthly.

their previous torpor, this is the hot fit. 4. The stomach and upper intestines have not acquired their natural quantity of senforial power of irritation, which was previously exhausted by violent action in consequence of the stimulus of contagious
matter, and the heart and arteries remain torpid from deficient excitement of the sensorial power of association, owing
to the too seeble actions of the stomach. 5. The accumulation
of sensorial power of association in consequence of the torpor of
the heart and arteries occasions a perpetual orgasm, or increased
action of the capillaries.

11. From hence it may be deducted first, that when the torpor of the stomach first occurs, either as a primary effect, or as a secondary link of some affociate train or circle of motions, a general torpor of the system sometimes accompanies it, which constitutes the cold sit of sever; at other times no such general torpor occurs, as during the operation of a weak emetic, or dur-

ing sea-sickness.

Secondly. After a time it generally happens, that a torpor of the stomach ceases, and its actions are renewed with increase of vigour by accumulation of sensorial power during its quiescence; as after the operation of a weak emetic, or at the intervals of sea-sickness, or after the paroxysm of an intermittent fever.

Thirdly. The stomach is sometimes much slower in recovering from a previous torpor, and is then the remote cause of continued sever with weak pulse; which is owing to a torpor of the heart and arteries, produced in consequence of the desicient excitement of the power of association by the too weak actions of the stomach; and to an orgasm of the capillaries of the other parts of the system, in consequence of the accumulation of sensorial power occasioned by the inactivity of the heart and arteries.

Fourthly. The torpor of the stomach is sometimes so complete, that probably the origin of its nerves is likewise affected, and then no accumulation of sensorial power occurs. In this case the patient dies for want of nourishment; either in three or sour weeks, of the inirritative sever; or without quick pulse, by what we have called paresis irritativa. Or he continues many years in a state of total debility. When this torpor suddenly commences, the patient generally suffers epileptic sits or temporary infanity from the disagreeable sensation of so great a torpor of the stomach; which also happens sometimes at the eruption of the distinct simall-pox; whence we have termed this disease anorexia epileptica. See Class II, 2, 2, 1, and III, 1, 1, 2, and Suppl. I. 14, 3.

Fifthly. When this torpor of the stomach is less in degree or extent, and yet without recovering its natural irritability by accumulation of sensorial power, as it does after the cold fit of intermittent sever, or after the operation of mild emetics, or during syncope; a permanent defect of its activity, and of that of the upper intestines, remains, which constitutes apepsia, cardialgia, hypochondriasis, and hysteria. See Class I. 3. 1. 3. and

Sixthly. If the torpor of the stomach be induced by direct sympathy, as in consequence of a previous torpor of the liver, or spleen, or skin, an accumulation of sensorial power will sooner be produced in the stomach; because there has been no previous expenditure of it, the present torpor of the stomach arising from defect of association. Hence some severes persectly intermit, the stomach recovering its complete action after the torpor and consequent orgasm, which constitute the paroxysm of sever, are terminated.

Seventhly. If the torpor of the stomach be owing to defect of irritation, as to the want of food, an accumulation of sensorial power soon occurs with an increase of digestion, if sood be timely applied; or with violent inflammation, if sood be given

in too great quantity after very long abstinence.

Eighthly. If the torpor of the stomach be induced by defect of pleasurable sensation, as when sickness is caused by the suggestion of nauseous ideas; an accumulation of sensorial power soon occurs, and the sickness ceases with the return of hunger; for in this case the inactivity of the stomach is occasioned by the subduction of agreeable sensation, which acts as a subduction of stimulus, and not by exhausting the natural quantity of sensorial

al power in the fibres or nerves of the stomach.

Ninthly. If the torpor of the stomach be induced by a two-fold cause, as in sea-sickness. See vertigo rotatoria. Class IV. 2. 1. 10. in which the first link of association acts too strongly, and in consequence expends more than usual of the sensorial power of irritation; and secondly in which sensation is produced between the links of association, and dissevers or enseebles them; the accumulation of sensorial power soon occurs in the stomach; as no previous expenditure of it in that organ has occurred. Whence in sea-sickness the persons take food with eagerness at times, when the vertigo ceases for a few minutes.

Tenthly. If the gastric torpor be induced by previous violent exertion, as after intoxication, or after contagious matter has been swallowed, or some poisons, as digitalis, or artenic; an accumulation of sensorial power very slowly succeeds; whence long fickness, or continued fever, because the quantity of sensorial power already wasted must first be renewed, before

an accumulation of it can be produced.

12. This leads us to a fecond indication of cure in continued fevers, which confifts in strengthening the actions of the stomach; as the first indication confisted in decreasing the actions of the cutaneous capillaries and absorbents. The actions of the stomach may sometimes be increased by exhibiting a mild emetic; as an accumulation of sensorial power in the sibres of the stomach is produced during their retrograde actions. Besides the evacuation of any noxious material from the stomach, and duodenum, and from the absorbents, which open their mouths on their internal surfaces, by their retrograde motion.

It is probable, that when mild emetics are given, as ipecacuanha, or antimonium tartarizatum, or infusion of camomile, they are rejected by an inverted motion of the stomach and resophagus in consequence of disagreeable sensation, as dust is excluded from the eye; and these actions having by previous habit been found effectual, and that hence there is no exhaustion of the sensorial power of irritation. But where strong emetics are administered, as digitalis, or contagious matter, the previous exhaustion of the sensorial power of irritation seems to be a cause of the continued retrograde actions and sickness of the stomach. An emetic of the former kind may therefore strengthen the power of the stomach immediately after its operation by the accumulation of sensorial power of irritation during its action. See Class IV. 1. 1.

Another method of decreasing the action of the stomach for a time, and thence of increasing it afterwards, is by the accumulation of the sentorial power of irritation during its torpor; is by giving ice, iced water, iced creams, or iced wine. This accounts for the pleasure, which many people in fevers with weak

pulse express on drinking cold beverage of any kind.

A fecond method of exciting the stomach into action, and of decreasing that of the capillaries in consequence, is by the stimulus of wine, opium, bark, metallic salts of antimony, steel, copper, arsenic, given in small repeated quantities; which so long as they render the pulse slower are certainly of service, and may be given warm or cold, as most agreeable to the patient. For it is possible, that the capillaries of the stomach may act too violently, and produce heat, at the same time that the large muscles of it may be in a torpid state; which curious circumstance suture observations must determine.

Thirdly. Hot fomentation on the region of the stomach might be of most essential service by its stimulus, as heat pene-

trates

trates the fystem not by the absorbent vessels, but by external influence; whence the use of hot somentation to the head in torpor of the brain; and the use of hot bath in cases of general debility, which has been much too frequently neglected from a popular error occasioned by the unmeaning application of the word relaxation to animal power. If the fluid of heat could be directed to pass through particular parts of the body with as little disfusion of its influence, as that of electricity in the shocks from the coated jar, it might be employed with still greater advantage.

Fourthly. The use of repeated small electric shocks through the region of the stomach might be of service in severs with weak pulse, and well deserves a trial; twenty or thirty small shocks twice a day for a week or two would be a promising ex-

periment.

Fifthly. A blifter on the back, or fides, or on the pit of the stomach, repeated in succession, by stimulating the skin frequently strengthens the action of the stomach by exciting the sensorial power of association; this especially in those severs where the skin of the extremities, as of the hands or nose or ears, soon-

er becomes cold, when exposed to the air, than usual.

Sixthly. The action of the stomach may be increased by preventing too great expenditure of sensorial power in the link of previous motion with which it is catenated, especially if the action of that link be greater than natural. Thus as the capillaries of the skin act too violently in severs with weak pulse, if these are exposed to cold air or cold water, the sensorial power, which previously occasioned their orgasm, becomes accumulated, and tends to increase the action of the stomach; thus in those severs with weak pulse and hot skin, if the stomach be stimulated by repeated small doses of bark and wine or opium, and be surther excited at the same time by accumulation of sensorial power occasioned by rendering the capillaries torpid by cold air or water, this twofold application is frequently attended with visible good effect.

By thus stimulating the torpid stomach into greater action, the motions of the heart and arteries will likewise be increased by the greater excitement of the power of affociation. And the capillaries of the skin will cease to act so violently, from their not possessing so great a superfluity of sensorial power as during the greater quiescence of the stomach and of the heart and arteries. Which is in some circumstances similar to the curious phenomenon mentioned in Class IV. 2. 2. 10.; where, by covering the chill seet with slannel at the eruption of the small-pox, the points of the slannel stimulate the skin of the seet into greater

Vol. II. PPp action,

action, and the quantity of heat, which they possess, is also confined, or insulated, and further increases by its stimulus the activity of the cutaneous vessels of the feet; and by that circumstance abates the too great action of the capillaries of the face, and the consequent heat of it.

XIII. Case of continued Fever.

The following case of continued sever which I frequently saw during its progress, as it is less complicate than usual, may illustrate this doctrine. Master S. D. an active boy about eight years of age, had been in the snow for many days, and sat in the classical school with wet feet; he had also about a fortnight attended a writing school, where many children of the lower order were instructed. He was seized on February the 8th, 1795, with great languor, and pain in his forehead, with vomiting and perpetual sickness; his pulse weak, but not very frequent. He took an emetic, and on the next day had a blister, which checked the sickness only for a few hours; his skin became perpetually hot, and dry; and his tongue white and furred; his pulse when asserb about 104 in a minute, and when awake about 112.

Fourth day of the disease. He has had another blister, the pain of his head is gone, but the sickness continues by intervals; he refuses to take any solid food, and will drink nothing but milk, or milk and water, cold. He has two or three very liquid stools every day, which are sometimes green, but generally of a darkish yellow, with great flatulency both upwards and downwards at those times. An antimonial powder was once given, but instantly rejected; a spoonful of decoction of bark was also exhibited with the same event. His legs are bathed, and his hands and face are moistened twice a day for half an hour in warmish water, which is nevertheless much colder than his skin.

Eighth day. His skin continues hot and dry without any obfervable remissions, with liquid stools and much flatulency and sickness; his water when observed was of a straw colour. He has asked for cider, and drinks nearly a bottle a day mixed with cold water, and takes three drops of laudanum twice a day.

Twelfth day. He continues much the fame, takes no milk, drinks only cider and water, skin hot and dry, tongue hot and furred, with liquid stools, and sickness always at the same time;

fleeps much.

Sixteenth day. Was apparently more torpid, and once rath-

er delirious; pulse 112. Takes only capillaire and water; sleeps much.

Twentieth day. Pulse 100, skin dry but less hot, liquid stools not so frequent, he is emaciated to a great degree, he has eaten half a tea-cup full of custard to day, drinks only capillaire and water, has thrice taken two large spoonfuls of decoction of bark with three drops of laudanum, refuses to have his legs bathed, and will now take nothing but three drops of laudanum twice a day.

Twenty-fourth day. He has gradually taken more custard every day, and began to attend to some new playthings, and takes

wine fyllabub.

Twenty-eighth day. He daily grows stronger, eats eggs, and bread and butter, and sleeps immediately after his food, can creep on his hands and knees, but cannot stand erect.

Thirty-fecond day. He cannot yet stand alone fafely, but feems hourly to improve in strength of body, and activity of

mind.

In this case the remote cause of his sever could not be well ascertained, as it might be from having his seet cold for many successive days, or from contagion; but the latter seems more probable, because his younger brother became ill of a similar sever about three weeks afterwards, and probably received the infection from him. The disease commenced with great torpor of the stomach, which was shewn by his total aversion to solid food, and perpetual sickness; the watery stools, which were sometimes green, or of a darkish yellow, were owing to the acrimony, or acidity of the contents of the bowels; which as well as the slatulency were occasioned by indigestion. This torpor of the stomach continued throughout the whole sever, and when

it ceased, the fever ceased along with it.

The contagious material of this fever I suppose to have been mixed with the faliva, and swallowed into the stomach; that it excited the vessels, which constitute the stomach, into the greatest irritative motion like arsenic; which might not be perceived, and yet might render that organ paralytic or inirritable in a moment of time; as animals sometimes die by one single exertion, and consequent paralysis, without a second struggle; as by lightning, or being shot through the back part of the brain; of both which I have seen instances. I had once an opportunity of inspecting two oxen, a sew minutes after they were killed by lightning under a crab-tree on moist ground in long grass; and observed, that they could not have struggled, as the grass was not pressed or bent near them; I have also seen two horses shot through the cerebellum, who never once drew in their legs after

they

they first stretched them out, but died instantaneously; in a simbilar manner the lungs seem to be rendered instantly inanimate

by the fumes of burning fulphur.

The lungs may be fometimes primarily affected with contagious matter floating in the atmosphere as well as the stomach, as mentioned in article 9. of this Supplement. But probably this may occur much less frequently, because the oxygene of the atmosphere does not appear to be taken into the blood by animal absorption, as the faliva in the stomach, but passes through the moist membranes into the blood, like the ethereal sluids of electricity or heat, or by chemical attraction, and in consequence the contagious matter may be lest behind; except it may sometimes be absorbed along with the mucus; of which however in this case there appeared no symptoms.

The tonfils are other organs liable to receive contagious matter, as in the small-pox, scarlet-sever, and in other sensitive inirritated fevers; but no symptom of this appeared here, as the tonfils were at no time of the sever inslamed, though they were in this

child previously uncommonly large.

The pain of the forehead does not feem to have been of the internal parts of the head, because the nerves, which serve the stomach, are not derived from the anterior part of the brain; but it seems to have been owing to a torpor of the external membranes about the forehead from their direct sympaths with those of the stomach; that is, from the desicient excitement of the sensorial power of association; and seemed in some measure to be relieved by the emetics and blisters.

The pullations of the heart were weaker and in confequence quicker than natural, owing to their direct sympathy with the torpid peristaltic motions of the stomach; that is to the deficient

excitement of the fenforial power of affociation.

The action of the cutaneous capillaries and abforbents were stronger than natural, as appeared by the perpetual heat and dryneis of the skin; which was owing to their reverse sympathy with the heart and arteries. This weaker and quicker action of the heart and arteries, and the stronger action of the cutaneous capillaries and absorbents, continued throughout the disease, and may be said to have constituted the sever, of which the torpor of the stronger was the remote cause.

His tongue was not very much furred or very dry, nor his breath very hot; which shewed, that there was no great increase of the action of the mucous absorbents, nor of the pulmonary capillaries, and yet sufficient to produce great emaciation. His urine was nearly natural both in quantity and colour; which

fhewed,

shewed, that there was no increase of action either of the kid-

neys, or of the urinary absorbents.

The bathing his legs and hands and face for half an hour twice a day feemed to refresh him, and sometimes made his pulse flower, and thence I suppose stronger. This seems to have been caused by the water, though subtepid, being much below the heat of his skin, and consequently contributing to cool the capillaries, and by fatiating the abforbents to relieve the uneafy fenfation from the dryness of the skin.

He continued the use of three drops of tincture of opium from about the eighth day to the twenty-fourth, and for the three preceding days took along with it two large spoonfuls of an infusion of bark in equal parts of wine and water. The former of these by its stimulus seemed to decrease his languor for a time, and the latter to strengthen his returning power of di-

other party or pay the state of the The daily exacerbations or remissions were obscure, and not well attended to; but he appeared to be worse on the fourteenth or fifteenth days, as his pulse was then quickest, and his inattention greatest; and he began to get better on the twentieth or twenty-first days of his disease; for the pulse then became less frequent, and his skin cooler, and he took rather more food: these circumstances seemed to observe the quarter periods of lunation.

XIV. Termination of continued Fever.

1. When the stomach is primarily affected with torpor not by defect of stimulus, but in consequence of the previous exhaustion of its sensorial power; and not secondarily by its association with other torpid parts; it feems to be the general cause of the weak pulsations of the heart and arteries, and the confequent increased action of the capillaries, which constitute continued fever with weak pulse. In this lituation if the patient recovers, it is owing to the renovation of life in the torpid stomach, as happens to the whole system in winter-sleeping animals. If he perishes, it is owing to the exhaustion of the body for want of nourishment occasioned by indigestion; which is hastened by the increased actions of the capillaries and absorbents:

2. When the stomach is primarily affected by defect of stimulus, as by cold or hunger; or secondarily by defect of the power of affociation, as in intermittent fevers; or lastly in confequence of the introduction of the sensorial power of sensation; as in inflammatory diseases; the actions of the heart and arteries are not diminished, as when the stomach is primarily af-

fected with torpor by its previous exhaustion of sensorial power, but become greatly increased, producing irritative or inflammatory sever. Where this sever is continued, though with some remissions and exacerbations, the excessive action is at length so much lessened by expenditure of sensorial power, as to gradually terminate in health; or it becomes totally exhausted, and death succeeds the destruction of the irritability and affociability of the system.

3. There is also another termination of the diseases in confequence of great torpor of the stomach, which are not always termed severs; one of these is attended with so great and universal torpor, that the patient dies in the first cold sit; that is, within twelve hours or less of the first seizure; this is commonly termed sudden death. But the quickness of the pulse, and the coldness with shuddering, and with sick stomach, distinguished a case, which I lately saw, from the sudden deaths occasion-

ed by apoplexy, or ruptured blood-vessels.

In hemicrania I believe the stomach is always affected fecondarily, as no quickness of pulse generally attends it, and as the stomach recovers its activity in about two whole days. But in the following case, which I saw last week, I suppose the stomach fuddenly became paralytic, and caused in about a week the death of the patient. Miss ——, a fine young lady about nineteen, had bathed a few times, about a month before, in a cold fpring, and was always much indifposed after it; she was feized with fickness, and cold shuddering, with very quick pulse, which was succeeded by a violent hot fit; during the next cold paroxylm she had a convulsion fit; and after that fymptoms of infanity, fo as to strike and bite the attendants. and to speak furious language; the same circumstances occurred during a third fit, in which I believe a strait waistcoat was put on, and some blood taken from her; during all this time her stomach would receive no nutriment, except once or twice a little wine and water. On the seventh day of the disease, when I faw her, the extremities were cold, the pulse not to be counted, and she was unable to swallow, or to speak; a clyster was used with turpentine and musk and opium, with warm fomentations, but she did not recover from that cold fit.

In this case the convulsion sit and the infanity seem to have been violent efforts to relieve the disagreeable sensation of the paralytic stomach; and the quick pulse, and returning sits of torpor and of orgasim, evinced the disease to be attended with sever, though it might have been called anorexia maniacalis, or

epileptica.

4. Might not many be faved in these fevers with weak pulse

for a few weeks by the introduction of blood into a vein, once in two or three days; which might thus give further time for the recovery of the torpid stomach? Which seems to require some weeks to acquire its former habits of action, like the muscles of paralytic patients, who have all their habits of voluntary

affociations to form afresh, as in infancy.

If this experiment be again tried on the human subject, it should be so contrived, that the blood in passing from the well person to the sick one should not be exposed to the air; it should not be cooled or heated; and it should be measured; all which may be done in the following manner. Procure two filver pipes, each about an inch long, in the form of funnels, wide at top, with a tail beneath, the former fomething wider than a fwanquill, and the latter less than a small crow-quill. Fix one of these filver funnels by its wide end to one end of the gut of a chicken fresh killed about four or six inches long, and the other to the other end of the gut; then introduce the small end of one funnel into the vein of the arm of a well person downwards towards the hand; and laying the gut with the other end on a water-plate heated to 98 degrees in a very warm room, let the blood run through it. Then pressing the finger on the gut near the arm of the well person, slide it along so as to press out one gutful into a cup, in order to afcertain the quantity by weight. Then introduce the other end of the other funnel into a similar vein in the arm of the fick person upwards towards the shoulder; and by fliding one finger, and then another reciprocally, along the chicken's gut, so as to compress it, from the arm of the well person to the arm of the sick one, the blood may be meafured, and thus the exact quantity known which is given and received. See Class I. 2. 3. 25.

XV. Inflammation excited in Fever.

1. When the actions of any part of the fystem of capillaries are excited to a certain degree, sensation is produced, along with a greater quantity of heat, as mentioned in the fifth article of this supplement. When this increased capillary action becomes still more energetic, by the combined sensorial powers of sensation with irritation, new sibres are secreted, or new sluids, (which harden into sibres like the mucus secreted by the silk-worm, or spider, or pinna,) from which new vessels are constructed; it is then termed inslammation: if this exists in the capillary vessels of the cellular membrane or skin only, with seeble pullations of the heart and arteries, the febris sensitiva intraitata, or malignant sever, occurs; if the coats of the arteries

are also inflamed, the febris sensitiva irritata, or inflammatory fever, exists.

In all these fevers the part inflamed is called a phlegmon, and by its violent actions excites fo much pain, that is, fo much of the fenforial power of fenfation, as to produce more violent actions, and inflammation, throughout the whole system. Whence great heat from the excited capillaries of the skin, large and quick pulfations of the heart, full and hard arteries, with great univerfal fecretions and abforptions. These perpetually continue, though with exacerbations and remissions; which feem

to be governed by folar or lunar influence.

2. In this fituation there generally, I suppose, exists an increafed activity of the fecerning vessels of the brain, and confequently an increased production of sensorial power; in less violent quantity of this disease however the increase of the action of the heart and arteries may be owing simply to the accumulation of fenforial power of affociation in the stomach, when that organ is affected by fympathy with some inflamed part. In the fame manner as the capillaries are violently and permanently actuated by the accumulation of the fenforial power of affociation in the heart and arteries, when the stomach is affected primarily by contagious matter, and the heart and arteries fecondarily. Thus I suspect, that in the distinct small-pox the stomach is affected fecondarily by fympathy with the infected tonfils or inoculated arm; but that in the confluent fmall-pox the stomach is affected primarily, as well as the tonfils, by contagious matter mixed with the faliva, and fwallowed.

3. In inflammatory fevers with great arterial action, as the stomach is not always affected with torpor, and as there is a direct fympathy between the stomach and heart, some people have believed, that naufeating doses of some emetic drug, as of antimonium tartarizatum, have been administered with advantage, abating by direct sympathy the actions of the heart. This theory is not ill-founded, and the use of digitalis, given in small doses, as from half a dram to a dram of the saturated tincture, two or three times a day, as well as other less violent emetic drugs, would be worth the attention of hospital physicians.

In three cases of what I believed to be inflammatory rheumatism, two of them attended with pain of the side, and difficult respiration, and the other with swelled joints, after repeated venefections and moderate cathartics, and mild dofes of antimonials, without fuccess, the tincture of digitalis given in the fmall dose of ten drops every fix hours, appeared to abate the quickness and hardness of the pulse in two or three or four days, without inducing any degree of fickness.

Sickness

Sickness might also be produced probably with advantage by whirling the patient in a chair suspended from the ceiling by two parallel cords; which after being revolved sifty or a hundred times in one direction, would return with great circular velocity, and produce vertigo, similar I suppose to sea-sickness. And lastly the sickness produced by respiring an atmosphere mixed with one tenth of carbonated hydrogen, discovered by Mr. Watt, and published by Dr. Beddoes, would be well worthy exact and repeated experiment.

4. Cool air, cool fomentations, or ablutions, are also useful in this inflammatory fever; as by cooling the particles of blood in the cutaneous and pulmonary vessels, they must return to the heart with less stimulus, than when they are heated above the natural degree of ninety-eight. For this purpose snow and ice have been scattered on the patients in Italy; and cold bathing has been used at the eruption of the small-pox in China, and both, it is said, with advantage. See Class III. 2. 1. 12. and

Suppl. I. 8.

5. The lancet however with repeated mild cathartics is the great agent in destroying this enormous excitement of the system, so long as the strength of the patient will admit of evacuations. Blisters over the painful part, where the phlegmon of topical inflammation is situated, after great evacuation, is of evident service, as in pleurisy. Warm bathing for half an hour twice a day, when the patient becomes enseebled, is of great benefit, as in peripneumony and rheumatism.

6. When other means fail of fuccess in abating the violent excitement of the system in inflammatory diseases, might not the shaved head be covered with large bladders of cold water, in which ice or salt had been recently dissolved; and changed as often as necessary, till the brain is rendered in some degree torpid by cold?—Might not a greater degree of cold, as iced water;

or fnow, be applied to the cutaneous capillaries ?

7. Another experiment I have frequently wished to try, which cannot be done in private practice, and which I therefore recommend to some hospital physician; and that is, to endeavour to still the violent actions of the heart and arteries, after due evacuations by venesection and cathartics, by gently compressing the brain. This might be done by suspending a bed, so as to whirl the patient round with his head most distant from the centre of motion, as if he lay across a mill-stone, as described in Sect. XVIII. 20. For this purpose a perpendicular shaft armed with iron gudgeons might have one end pass into the floor, and the other into a beam in the ceiling, with an horizontal arm, to which a small bed might be readily suspended.

Vol. II. Qqq By

By thus whirling the patient with increasing velocity sleep might be produced, and probably the violence of the actions of the heart and arteries might be diminished in inflammatory fevers; and, as it is believed, that no accumulation of sensorial power would succeed a torpor of the origin of the nerves, either thus procured by mechanical compression, or by the bladdercap of cold water above described, the lives of thousands might probably be saved by thus extinguishing the exacerbations of febrile paroxysms, or preventing the returns of them.

In fevers with weak pulse sleep, or a degree of stupor, thus produced, might prevent the too great expenditure of sensorial power, and thus contribute to preserve the patient. See Class I. 2. 5. 10. on stupor. What might be the consequence of whirling a person with his head next the centre of motion, so as to force the blood from the brain into the other parts of the body, might be discovered by cautious experiment without danger, and might probably add to our ability of curing sever.

Mr. Kelly, in his observations on compression, Edinb. 1797, afferts, that by compressing the two subclavian arteries, as they pass over the first rib, more blood will compress the brain, and produce a kind of apoplectic state similar to that, which may occur by the centrifugal force, if the patient was whirled round as above described. And adds, that by this compression of the two subclavian arteries a greater quantity of blood will be circulated through the head, whence the patient soon complains of drowsiness and vertigo; and that hence different species of head-achs are soon removed, especially those which depend on defect of stimulation.

XVI. Recapitulation.

1. The fenforial power causes the contraction of the fibres, and is excited into action by four different circumstances, by the stimulus of external bodies, by pain or pleasure, by desire or aversion, or by the previous motions of other contracting fibres. In the first situation it is called the sensorial power of irritation, in the second the sensorial power of sensorial power of volition, and in the fourth the sensorial power of association.

Many parts of the body are excited into perpetual action, as the fanguiferous veffels confifting of the heart, arteries, and veins; others into nearly perpetual action, as the conglomerate and capillary glands; and others into actions still fomewhat less frequent, as the alimentary canal, and the lacteal and lymphatic absorbents with their conglobate glands: all these are principally actuated by the fenforial powers of irritation, and of affociation; but in some degree or at some times by those of fensation, and even of volition. There are three kinds of stimulus, which may easily be occasionally diminished, that of heat on the skin, of food in the stomach, and of the oxygenous part of the atmosphere, which mixes with the blood in respiration, and stimulates the heart and arteries.

2. When any parts, which are naturally excited into perpetual action by stimulus, become torpid or less active from decrease of that stimulus; there first occurs a decrease of the activity of the parts next catenated with them; thus going into cold water, produces a torpor of the capillary vessels of the lungs, as is known by the difficult respiration, which immediately occurs; for the sensorial power of affociation, which naturally contributes to actuate the lungs, is now less excited by the decreased actions of the cutaneous vessels, with which they are catenated. This constitutes the cold fit of fever.

There next occurs an accumulation of the fenforial power of irritation in the parts, which were torpid from defect of stimulus, as the cutaneous veffels for instance when exposed to cold air; and a fimilar accumulation of the fenforial power of afforciation occurs in the parts which were catenated with the former, as the vessels of the lungs in the example above mentioned. Whence, if the subduction of stimulus has not been too great, so as to impair the health of the part, the activity of the irritative motions returns, even though the stimulus continues less than usual; and those of the affociate motions become considerably increased, because these latter are now excited by the previous fibrous motions, which now act as strong or stronger than formerly, and have also acquired an accumulation of the sensorial power of affociation. This accounts for the curious event of our becoming warm in a minute or two after remaining in water of about 80 degrees of heat, as in the bath at Buxton; or in the cold air of a frosty morning of about 30 degrees of heat.

But if the parts thus possessed of the accumulated sensorial powers of irritation and of affociation be exposed again to their natural quantity of stimulus, a great excess of activity supervenes; because the sibres, which possess accumulated irritation, are now excited by their usual quantity of stimulus; and those which possess accumulated association, are now excited by double or treble the quantity of the preceding irritative sibrous motions, with which they are catenated; this constitutes the hot

fit of fever.

Another important circumstance occurs, when the parts, which are torpid from decreased stimulus, do not accumulate a

quantity of fenforial power fufficient for the purpose of renewing their own natural quantity of action; but are nevertheless not fo torpid, as to have the life of the part impaired. In this fituation the superabundance of the accumulated power of irritation contributes to actuate the affociate motions next catenated with them. Thus, when a person breathes air with less oxygene than natural, as by covering his head in bed, and thus respiring the same atmosphere repeatedly, the heart and arteries become less active by defect of the stimulus of oxygene; and then the accumulation of fenforial power of irritation becomes instantly very great, as these organs are subject to perpetual and energetic action. This accumulation nevertheless is not so great as to renew their own activity under this defect of stimulus, but yet is in sufficient abundance to increase the affociability of the next link of catenation, that is, to actuate the capillaries of the skin with great and perpetual increase of energy. This resembles continued fever with weak pulse; in which the accumulation of the fenforial power caused by the lessened motions of the heart and arteries, actuates the capillaries with increase of energy.

3. When the accumulation of the sensorial power of association, which is caused as above explained by deficient excitement owing to the lessened quantity of action of the irritative fibrous motions, with which the affociate train is catenated, is not in quantity fufficient to renew the natural actions of the first link of an affociate train of motions; it is nevertheless frequently fo abundant as to actuate the next link of the affociated train with unnatural energy by increasing its affociability; and that in a still greater degree if that second link of the associated train was previously in a torpid state, that is, had previously acquired some accumulation of the sensorial power of affociation. This important circumstance of the animal economy is worthy our most accurate attention. Thus if the heart and arteries are deprived of their due quantity of the stimulus of oxygene in the blood, a weak and quick pulse ensues, with an accumulation of the fenforial power of irritation; next follows an increase of the action of the capillaries by the superabundance of this accumulated power of irritation; but there also exists an accumulation of the power of affociation in these acting capillaries, which is not now excited by the deficient actions of the heart and arteries; but which by its abundance contributes to actuate the next link of affociation, which is the fick stomach in the case related from Sydenham in Class IV. 1. 1. 2. and explained in this Supplement I. 4. And as this fick stomach was in a previous state of torpor, it might at the same time possess an accumulation of some sensorial power, which, if it was of affociation, would be thus more powerfully excited by the increased actions of the capillaries; which existed in consequence of the weak action of the heart and arteries. This also resembles in some respects the continued severs with weak pulse, and with increase

ed activity of the capillaries.

. 4. When a torpor of some irritative motions occurs from a previous exhaustion of the sensorial power of irritation by the action of fome very great stimulus, it is long before any accumulation of the fenforial power of irritation is produced; as is experienced in the fickness and languor, which continues a whole day after a fit of drunkenness. But nevertheless there occurs an accumulation of the fenforial power of affociation in the first link of the affociate train of motions, which is catenated with these torpid irritative ones; which accumulation is owing to deficient excitement of that fenforial power in the first link of the affociate train. This first link therefore exists also in a less active or torpid state, but the accumulation of the fensorial power of affociation by its superabundance contributes to actuate the second link of the affociate train with unnatural quantity of motion; and that though its own natural quantity of the power of affociation is not excited by the deficient action of preceding fibrous motions.

When this happens to the stomach, as after its irritative motions have been much exerted from the unnatural stimulus of wine, or opium, or of contagious matter mixed with the faliva, a torpor or inactivity of it succeeds for a greater or less length of time; as no accumulation of the fenforial power of irritation can occur, till the natural quantity, which has been previously expended, is first restored. Then the heart and arteries, which are next in catenation, become less active from the want of sufficient excitement of the fenforial power of affociation, which previously contributed to actuate them. This sensorial power of affociation therefore becomes accumulated, and by its superabundance contributes to actuate the link next in affociation, which has thus acquired fo great a degree of affociability, as to overbalance the less quantity of the excitement of it by the torpid action of the previous or first affociate link. This happens to the capillaries, when the heart and arteries are affected as above by the torpor of the stomach, when it is occasioned by previous great expenditure of its fenforial power, and thus constitutes fever with weak pulse, which is here termed inirritative fever, typhus mitior.

5. When a deficiency of stimulus is too great or too long continued, so as to impair the life of the part, no further accumulation of sensorial power occurs; as when the skin is long ex-

posed to cold and damp air. In that case the link in catenation, that is, the first of the affociate train, is rendered torpid by defect of excitement of its usual quantity of the sensorial power of affociation, and from there being no accumulation of the sensorial power of irritation to increase its affociability, and thus to contribute to accurate it by overbalancing the defect of the excitement of its affociation.

Thus on riding long and flowly on a cold and damp day, the exhalation of the vapour, which is impinged on the skin, as the traveller proceeds, carries away his warmth faster, than it is generated within the fystem; and thus the capillaries of the skin have their actions fo much impaired after a time, that no accumulation of the fenforial power of irritation occurs; and then the stomach, the motions of which are catenated with those of the capillaries, ceases to act from the deficient excitement of the power of affociation; and indigestion and flatulency succeed, instead of the increased digestion and hunger, which occur, when the cutaneous capillaries are exposed to a less degree of cold, and for a shorter time. In which latter situation the accumulation of the fenforial power of irritation increases by its fuperabundance the affociability of the fibres of the stomach, so as to overbalance the defect of the excitement of their affociation.

6. The stomach is affected secondarily in fevers with strong pulse, as in those with weak pulse it is affected primarily. To illustrate this doctrine I shall relate the following case of Mr. of wine or beer, and was seized with a cold fit, and with a confequent hot one with ftrong pulse; on examining his hypochondrium an oblong tumour was distinctly felt on the left side of the stomach, which extended fix or eight inches downward, and was believed to be a tumour of the spleen, which thus occasioned by its torpor the cold fit and consequent hot fit of fever with strong pulse. This fever continued, though with remissions, for two or three weeks; and the patient repeatedly lost blood, used cathartics with calomel and senna, and had frequent antimonial and faline medicines. And after he was much weakened by evacuations, the peruvian bark and fmall doses of steel removed the fever, but the tumour remained many years during the remainder of his life.

In this case the tumour of the spleen was occasioned by the torpor of the absorbent vessels; while the secerning vessels continued somewhat longer to pour their sluids into the cells of it. Then the inactivity of this viscus affected the whole system with torpor by the descient excitement of the sensorial power of association

ciation, which contributes along with the irritation caused by their specific stimuli to actuate the whole sanguiserous, secerning, and absorbent vessels; and along with these the stomach, which possesses greater mobility, or promptitude to torpor or to orgasm, than any other part. And after a time all these parts recover their actions by the accumulation of their sensorial power of association. But the spleen not recovering its action from the accumulation of its power of irritation, as appeared from the continuance of the tumour, still affects the stomach by its defective irritative motions cealing to excite the association, which ought to contribute to actuate it.

Hence the stomach continues torpid in respect to its motions, but accumulates its power of association; which is not excited into action by the desective motions of the spleen; this accumulation of the sensorial power of association now by its superabundance actuates the next link of associate motions, which consists of the heart and arteries, into greater energy of action than natural, and thus causes sever with strong pulse; which, as it was supposed to be most frequently excited by increase of

irritation, is called irritative fever or fynocha.

Similar to this in the small-pox, which is given by inoculation, the stomach is affected secondarily, when the sever commences; and hence in this small-pox the pulsations of the heart and arteries are frequently stronger than natural, but never weaker, for the reasons above given. Whereas in that small-pox, which is caused by the stomach being primarily affected, by the contagious matter being swallowed with the saliva, whether the tonsils are at the same time affected or not, the pulsations of the heart and arteries become weak, and the inirritative sever is produced, as explained above, along with the consluent small-pox. This unfolds the cause of the mildness of the inoculated small-pox; because in this disease the stomach is affected secondarily, whereas in the natural small-pox it is frequently affected primarily by swallowing the contagious matter mixed with saliva.

In the measles I suppose the contagious matter to be dissolved in the air, and therefore not liable to be mixed with the saliva; whereas the variolous matter is probably only diffused in the air, and thence more readily mixed with the saliva in the mouth during respiration. This difference appears more probable, as the small-pox I believe is always taken at a less distance from the diseased person than is necessary to acquire the measles. The contagion of the measles affects the membranes of the nostrils, and the secretion of tears in consequence, but never I suspect the stomach primarily, but always secondarily; whence the pul-

fation of the heart and arteries is always stronger than natural, fo as to bear the lancet at any period of the disease.

The great mildness sometimes, and fatality at other times, of the scarlet sever may depend on the same circumstance; that is, on the stomach being primarily or secondarily affected by the contagious matter, observing that the tonsils may be affected at the same time with the stomach. Should this prove to be the case, which suture observations must determine, what certain advantage must arise from the inoculation of this disease! When it is received by the skin primarily I suppose no fore throat attends it, nor sever with weak pulse; when it is received by the stomach primarily, the tonsils are affected at the same time, and the torpor of the stomach produces inirritative sever, and the mortification of the tonsils succeeds.

We may hence conclude, that when the torpor of the stomach is either owing to defect of stimulus, which is not so great as to impair the life of the part, as in moderate hunger, or in fwallowing iced water, or when its torpor is induced by its catenation or affociation with other torpid parts, as in the commencement of intermittent fevers, and inoculated fmall-pox, that the subsequent action of the heart and arteries is generally increafed, producing irritative fever. Which is owing to the accumulation of the fenforial power of irritation in one case, and of affociation in the other, contributing to actuate the next link of the catenated or affociated motions. But when the torpor of the stomach is induced by previous exhaustion of its sensorial powers of irritation or of affociation by continued violent action, as by the stimulus of digitalis, or of contagious matter, or after intoxication from wine or opium, a weaker action of the heart and arteries succeeds, because there is no accumulation of senforial power, and a deficient excitement of affociation. And finally, as this weak action of the heart and arteries is not induced by exhaustion of sensorial power, but by defect of the excitement of affociation, the accumulation of this power of affociation increases the action of the capillaries, and thus induces inirritative fever.

7. When any part of the fystem acts very violently in fevers, the sensorial power of sensation is excited, which increases the actions of the moving system: whereas the pain, which arises from decreased irritative motions, as in hemicrania, seems to exhaust a quantity of sensorial power, without producing or increasing any sibrous actions.

When the stomach is primarily affected, as in inirritative fevers from contagion, and in such a manner as to occasion pain, the action of the capillaries seems to be increased by this additional

fenforial

fenforial power of fenfation, whence extensive inflammation or mortification; but when the stomach and consequently the heart and arteries continue their torpidity of action; as in consuent small-pox, and stall scarlatina; this constitutes sensitive inirri-

tative fever, or typhus gravior.

But when the stomach is secondarily affected, if the sensorial power of sensation is excited, as in pleurify or peripneumony, the actions of the heart and arteries are violently increased, and of all the moving system along with them. Thus the peripneumony is generally induced by the patient respiring very cold air, and this especially after being long confined to warm air, or after being much satigued and heated by excessive labour or exercise. For we can cover the skin with more clothes, when we seel ourselves cold; but the lungs not having the perception of cold, we do not think of covering them, nor have the power to cover them, if we desired it; and the torpor thus produced is greater, or of longer duration, in proportion to the previous expenditure of sensorial power by heat or exercise.

This torpor of the lungs affects the skin with shuddering, and the stomach is also secondarily affected; next follows the violent action of the lungs from the accumulation of the power of irritation, and an inflammation of them follows this violent action. While the stomach recovers its activity by the increase of the excitement of the sensorial power of association, and along with it the heart and arteries, and the whole moving system. Hence this inflammation occurs during the hot sit of sever, and no cold sit succeeds, because the excess of the sensorial power of sensorial

tion prevents a fucceeding torpor.

These new motions of certain parts of the system produce increased secretions of nutritious or organic mucus, which forms new vessels; these new vessels by their unusual motions produce new kinds of sluids; which are termed contagious, because they have the power, when introduced into a healthy body, of producing similar actions and effects, with or without sever, as in the small-pox and measles, or in the itch and venereal disease.

If any of these contagious matters affect the stomach with torpor either by their stimulus immediately applied, or by its sympathy with the parts sirst diseased, a sever is produced with sickness and want of appetite; as in small-pox, and scarlatina. If the stomach is not affected by contagious matter, no sever suc-

ceeds, as in itch, tinea, syphilis.

Ali these contagious matters are conceived to be harmless, till they have been exposed to the air, either openly or through a mount membrane; from which they are believed to acquire oxygene, and thence to become some kinds of animal acids. As

Vol. II. RRr the

the preparations of mercury cure venereal ulcers; as a quarter of a grain of fublimate diffolved in wine, and given thrice a day; this effect feems to be produced either by its stimulating the absorbents in the ulcer to absorb the venereal matter before it has acquired oxygene; or by afterwards uniting with it chemically, and again depriving it of its acquired acidity. On either fupposition it might probably be given with advantage in smallpox, and in all infectious difeases, both previous to their com-

mencement, and during their whole progrefs.

8. The cold fits of intermittent fevers are caused by the torpor of some part owing to deficient irritation, and of the other parts of the fystem from deficient association. The hot fits are owing first to the accumulation of irritation in the part primarily affected, if it recovers its action, which does not always happen; and fecondly to the accumulation of affociation in the other parts of the fyltem, which during health are subject to perpetual action; and laftly also to the greater excitement of the power of affociation, when the part primarily affected recovers its irritability, and acts with greater energy than natural.

The deficient fecretions in the cold fit depend on the torpor of the glandular fystem; and the increased secretions in the hot fit on their more energetic action. The thirst in the cold fit is owing to the deficient absorption from the skin, cellular membrane, and bladder; the thirst in the hot fit is owing to the too great diffipation of the aqueous part of the blood. The urine is pale and in small quantity in the cold fit from deficient secretion of it, and from deficient absorption of its aqueous parts; it is high coloured, and fometimes deposits a fediment, in the hot fit from the greater fecretion of it in the kidneys, and the greater absorption of its aqueous and faline part in the bladder. The dryness and scurf on the tongue and nostrils are owing to the increased heat of the air expired from the lungs, and consequent greater evaporation of the aqueous part of the mucus. The fweats appear in consequence of the declension of the hot fit, owing to the absorbent vessels of the skin losing their increased action fooner than the fecerning ones; and to the evaporation leffening as the skin becomes colder. The returns of the paroxysms are principally owing to the torpor of some less effential part of the fystem remaining after the termination of the last fit; and are also dependent on solar or lunar diurnal periods.

The torpor of the part, which induces the cold paroxysm, is owing to deficient irritation occasioned either by the subduction of the natural stimuli of food, or water, or pure air, or by deficiency of external influences, as of heat, or of folar or lunar gravitation. Or fecondly, in confequence of the exhaustion of

fenforial power by great previous exertions of some parts of the. fystem, as of the limbs by great labour or exercise, or of the ftomach by great stimulus, as by contagious matter swallowed with the faliva, or by much wine or opium previously taken into it. Or lastly a torpor of a part may be occasioned by some mechanic injury, as by a compression of the nerves of the part, or of their origin in the brain; as the fitting long with one leg croffed over the other occasions numbness, and as a torpor of the stomach with vomiting frequently precedes paralytic strokes of the limbs.

As fleep is produced, either by defect of stimulus, or by previous exhaustion of sensorial power; so the accumulation of the fenforial power of volition in those muscles and organs of sense, which are generally obedient to it, awakens the fleeping person; when it has increased the quantity of voluntarity so much as to overbalance the defect of stimulus in one case, and the exhaustion of fenforial power in the other; which latter requires a much longer time of fleep than the former. So the cold paroxysm of fever is produced either by defect of stimulus, or by previous exhaustion of the sensorial power of some part of the fystem; and the accumulation of the sensorial power of irritation in that part renews the action of it, when it has increased its irritability fo much as to overbalance the defect of stimulus in one case, and the exhaustion of sensorial power in the other; which latter requires a much longer torpor or cold fit than the former.

But in the cold paroxysm of fever, besides the torpor of one part of the system from defect of irritation, the remainder of it. becomes torpid owing to defect of excitement of the fenforial power of affociation by the leffened action of the part first affected. This torpor of the general system remains, till the accumulation of the sensorial power of association has increased the asfociability fo much as to overbalance the defect of the excitement of affociation; then the torpor ceases, and if the first affected part has recovered its activity, the other parts are all thrown into excess of action by their increased affociability, and the hot fit of fever is produced.

o. In the continued fevers with strong pulse the stomach is affected fecondarily, and thus acts feebly from deficient excitement of the power of affociation; but the accumulation of the power of affociation thus produced in an organ subject to perpetual and energetic action, is so great as to affect the next link of the affociate train, which confifts of the heart and arteries; these therefore are exerted perpetually with increase of action.

In continued fevers with weak pulle the torpid stomach is af-

fected

fected primarily by previous exhaustion of its irritability by stimulus, as of contagious matter swallowed into it. The heart and arteries act feebly from desicient excitement of the power of affociation, owing to the torpor of the stomach, with which they are catenated; but the accumulation of the power of affociation, thus produced in organs subject to perpetual and energetic motion, is so great, as to affect the next link of the affociate train; which consists of the capillaries of the skin or other glands; these therefore are exerted perpetually with great increase of action.

The continued fevers with strong pulse terminate by the reduction or exhaustion of the sensorial power by violent action of the whole system; which is followed either by return of health with the natural quantity of irritability, and of associability, or by a total destruction of them both, and consequent

death.

In continued fevers with weak pulse the stomach remains torpid during the whole course of the sever; and at length by the recovery of its irritability and sensibility effects the cure of it. Which generally happens about the first, second, or third quarter of the lunar period, counted from the commencement of the disease, or continues a whole lunation, and sometimes more; which gave rise to what are termed critical days. See Sect. XXXVI. 4. on this subject. If the stomach does not recover from its torpor, the patient becomes emaciated, and dies exhausted by the continuance of the increased action of the capillaries and absorbents, and the want of nourishment.

The cure of continued fever with weak pulse consists first in weakening the undue action of the capillaries of the skin by ablution with cold water from 32 to 80 degrees of heat; or by exposing them to cool air. Secondly by invigorating the actions of the stomach, by decreasing them for a time, and thence accumulating the power of irritation, as by an emetic, or by iced water, or iced wine. Or by increase of stimulus, as by bark, wine, opium, and food, in small quantities frequently repeated. Or by renewing the action of the stomach by slight electric shocks. Or by somenting it frequently with water heated to 96 or 100 degrees. Or lastly by exciting its power of association with other parts of the system, as by a blister; which succeeds best when the extremities are cool; or by swinging, as in vertigo rotatoria.

If by the stimulus of the Peruvian bark on the sibres of the stomach, they regain their due action, the heart and arteries also regain their due action; as their sensor of association is now excited, and expended as usual. And as there is then no accumulation of sensorial power in the heart and arteries, the

capillaries

capillaries cease to act with too great energy, and the sever is cured.

Thirdly. If the heart and arteries could be themfelves stimulated into greater action, although the stomach remained torpid, they might probably by expending a greater quantity of the sensorial power of irritation, prevent an accumulation of the sensorial power of association, (for these may possibly be only different modes of action of the spirit of animation,) and thus the too great action of the capillaries might be prevented and the sever cease. This new mode of cure might possibly be accomplished, if the patient was to breathe a gallon or two of pure or diluted oxygene gas frequently in a day; which by passing through the moist membranes of the lungs and uniting with the blood might render it more stimulant, and thus excite the heart

and arteries into greater action.

Fourthly. Greater energy might probably be given to the whole system, and particularly to those parts which act too feebly in fevers, as the stomach and the heart and arteries, if the action of the fecerning vessels of the brain could be increased in energy; this is probably one effect of all those drugs, which when given in large quantity induce intoxication, as wine and opium. And when given with great caution in small quantities uniformly repeated, as from three drops to five of the tincture of opium, but not more, every fix hours, I believe they fupply an efficacious medicine in fevers with great arterial debility; and the more so, if the Peruvian bark be exhibited alternately every fix hours along with them. There are other means of exciting the veffels of the brain into action; as first by decreasing the stimulus of heat by temporary cold fomentation; secondly, increasing the stimulus of heat by long continued warm fomentation; thirdly, by electricity, as very small shocks passed through it in all directions; and lastly by blisters on the head. All those require to be used with great caution, and especially where there exists an evident stupor, as the removing of that is I believe frequently injurious. See stupor, Class I. 2. 5. 10.

The cure of fever with strong pulse consists in the repeated use of venesection, gentle cathartics, diluents; medicines producing sickness, as antimonials, digitalis; or the respiration of carbonated hydrogen; or by respiration of atmospheric air lowered by a mixture of hydrogen, azote, or carbonic acid gas, or by compressing the brain by whirling in a decumbent posture, as if lying across a horizontal mill-stone. See the former parts of this supplement for the methods of cure both of severs with

ftrong and weak pulse.

10. When any difficulty occurs in determining the weak

pulse from the strong one, it may generally be assisted by counting its frequency. For when an adult patient lies horizontally in a cool room, and is not hurried or alarmed by the approach of his physician, nor stimulated by wine or opium, the strong pulse sededoms exceeds 118 or 120 in a minute; and the weak pulse is generally not much below 130, and often much above that number; except where a patient has naturally a pulse slower than usual in his healthy state. Secondly in sitting up in bed, or changing the horizontal to a perpendicular posture, the quickness of the weak pulse is liable immediately to increase 10 or 20 pulsations in a minute, which does not I believe occur in the strong pulse, when the patient has rested himself after the exertion of rising.

I shall here insert a remark on the general use of stimulating materials, whether medicinal or culinary, to counteract or prevent debility. When a flimulating material is exhibited, as the Peruvian bark, or opium, or wine; it should be continued but a certain time, as half a lunation, or a whole lunation. If the whole fystem be stimulated into increased exertion, as by wine or opium, there appears to be a temporary increased secretion of fenforial power in the brain, so long as this stimulus affects the fystem. If a part only of the system be stimulated, as by the exhibition of spices, essential oils, or bitter medicines, or metallic ones, then the stimulated organ has derived to it a greater quantity of fenforial power, or a greater fecretion of it is produced in that part of the brain, where the stimulated nerves arife. Which is probably owing to the fympathy of the stimulated extremity of every nerve, or its organ of fense, with the other extremity of it in the brain, in the fame manner as when the excretory duct of a gland is stimulated, a greater secretion is produced in the body of it, as when the ducts of the lacrymal glands in the eyes, or of the falivary glands in the mouth are stimulated by dust or acrid materials.

Now if a stimulating medicine be given at certain intervals of time, as the Peruvian bark or wine in fevers, the increased action of a part or of the whole system soon becomes a link of the associated circle of diurnal actions, and may be said to be-

come habitual.

The quantity of the stimulating medicine may then be diminished, and yet the increased activity of the system will continue; because the increased exertions are now produced partly by the sensorial power of association, as they are become a part of the diurnal circle of actions. And finally the stimulating medicine may be totally omitted, and yet the increased activity of the system continue for the same reason.

On

On this circumstance depends the power of the bitter medicines, as the bark, and other stimulating materials, as beer and wine, in preventing the returns of the cold paroxysins of fevers, and in strengthening the system, which increase of irritability, that is of strength, continues after the use of the medicine is withdrawn.

But on the contrary, if the stimulating material be continued much longer than one lunation, the whole system, or the stimulated organ alone, is excited into too forcible action by the two sensorial powers of irritation, and of association; and consequently in process of time loses in some degree both its irritability and its associability; and inactivity or torpor succeeds; which constitutes weakness, as is seen in all those, who accustom themselves to dram-drinking.

Hence wine or opium, or Peruvian bark, may be continued twice or four times a day for half a lunation, or for a whole one with advantage in diseases of debility, for the purpose of gaining both diurnal and monthly associations of activity. But should not be much longer continued; as a consequent debility

will then be liable to fucceed.

XVII. Conclusion.

Thus have I given an outline of what may be termed the fympathetic theory of fevers, to distinguish it from the mechanic theory of Boerhaave, the spasmodic theory of Hossman and of Cullen, and the putrid theory of Pringle. What I have thus delivered, I beg to be considered rather as observations and conjectures, than as things explained and demonstrated; to be considered as a foundation and a scassoding, which may enable future industry to erect a solid and a beautiful edisice, eminent both for its simplicity and utility, as well as for the permanency of its materials,—which may not moulder, like the structures already erected, into the sand of which they were composed; but which may stand unimpaired, like the Newtonian philosophy, a rock amid the waste of ages!
